Developed land changes the hydrology of sites, leading to higher stormwater discharge volumes and higher pollutant loads. The purpose of this standard is to maintain or restore stable hydrology in receiving waters thereby protecting water quality by having post-construction hydrology mimic the natural hydrology of the area.

A simpler, but reasonably approximate 'mimicking the natural hydrograph' approach can typically be accomplished by retaining (as opposed to detaining stormwater for later discharge) on a developed site the volume of water that was retained prior to development, through the mechanisms of infiltration, evapotranspiration, and capture and use. By significantly reducing the volume of stormwater discharges, these mechanisms significantly reduce the discharge of pollutants in stormwater, making discharge volumes the ideal all-around focus and metric for stormwater management. These provisions must be clear about the retention requirement, e.g., an underdrained rain garden likely functions more as a detention and filtration system than an infiltration system.

In Part 5.2.3, the five types of development which qualify for incentives are redevelopment, brownfield redevelopment, high density, vertical density, and mixed use with transit oriented development. Redeveloping already degraded sites can reduce regional land consumption and minimize new land disturbance. Minimizing land disturbance and impervious cover is critical to maintaining watershed health. In addition to water quality benefits, cleaning up and reinvesting in brownfield properties increases local tax bases, facilitates job growth, utilizes existing infrastructure, takes development pressures off of undeveloped, open land, and both improves and protects the environment. The effect of low-density urbanization on watersheds and the hydrologic cycle is substantial. High-density development, including vertical density, slows land consumption rates and accommodates more land uses on a smaller footprint. Finally, mixing land uses and promoting transit-oriented development can directly reduce runoff since mixed-use developments have the potential to use surface parking lots and transportation infrastructure more efficiently, requiring less pavement.¹⁹

In Part 5.2.4.d, the permittee must establish clear and stringent criteria for the conditions under which payment in lieu and off-site mitigation could be used. These criteria must be related to physical constraints such as a combination of soils which limit infiltration opportunities, space or light limited situations restricting the amount of vegetation that can be used, and a land use that is not conducive to capture and use of stormwater. Further, appropriate schedules for

¹⁸ *West Virginia Small MS4 Permit (Section C.b.5.a.ii.A.4)*
(www.wvdep.org/Docs/17444_SW_WV%20MS4%20permit%202009.pdf)

¹⁹ Adapted from the WV Phase II MS4 Fact Sheet
(www.dep.wv.gov/WWE/Programs/stormwater/MS4/permits/Pages/default.aspx)

MS4 Permit Improvement Guide

payment and implementation of mitigation measures must be established to ensure stormwater impacts are addressed in a timely manner.

Recommendations for Permit Writer

Many communities have adopted criteria based on already promulgated flood-control based standards (i.e., focused only on discharge rates). This example permit language instead promotes the concept that effective standards should be based on the objective of maintaining or restoring stable hydrology to protect the quality of receiving waters by having post-construction hydrology mimic the natural hydrology of the area. The permit language provides a number of example standards that can be used to achieve this objective.

Performance standards should take into account the wide variability in hydrologic conditions in different areas. Ideally, standards should reflect the local naturally-occurring hydrology with respect to runoff, infiltration, evapotranspiration, and storage – that is, the water balance that would be present in the absence of development. Key parameters, such as rainfall patterns, soil characteristics, and topography, can be used to establish likely 'natural' hydrology. Where maintaining or reestablishing such hydrologic conditions is infeasible, off-site mitigation, payment-in-lieu, or fee programs may be used. Based on current (2010) information, EPA recommends that permits allow for a combination of techniques that utilize infiltration, capture and use, and evapotranspiration as appropriate, rather than relying only on infiltration or some other technique alone to meet performance standards.

The permit writer could include a performance standard that stipulates that predevelopment hydrographs match post-development hydrographs. In order for this type of performance standard to be effective, the permit writer should make sure that the permit clearly spells out all variables of the hydrograph (volume, rate, duration, frequency) to be matched, and not just the discharge rate. Many current pre-post hydrology standards focus only on discharge rate, which is primarily a flood control approach. In addition, a pre-development condition should also be defined, and that condition should be one that is reasonably 'natural', rather than simply the conditions (perhaps already fairly impervious) that existed immediately prior to the current developed site. A calculator tool based on key hydrologic parameters (soil, rainfall, slope, and vegetation) or an on-site rainfall retention standard that is appropriate for that area can help the permittee determine what constitutes pre-development hydrology and the means by which it may be matched.

As contemplated in the example permit provisions, permit writers may want to consider the difference between new development and redevelopment sites, as well as differences among some types of developed sites, in establishing performance standards. From the standpoint of imperviousness at a watershed scale, redeveloped sites are usually more desirable than new development sites, which replace relatively naturally functioning green spaces with impervious surfaces such as roads, and parking lots. Certain types of development generate less impervious surfaces than others. For example, typically, there is little or no increase in net stormwater discharges when redeveloping underused properties such as vacant properties, brownfield sites, or greyfield sites, since new impervious cover replaces existing impervious cover. The net discharge increase from already developed properties would likely be zero since the site was already predominately impervious cover. In many cases, redeveloped sites break up or remove some portion of the impervious cover, converting it to pervious cover and allowing for some stormwater infiltration. Redevelopment sites can produce a net improvement in regional water quality by decreasing total impervious area and its

MS4 Permit Improvement Guide

associated stormwater discharges. Redeveloped sites can also reduce regional land consumption. By building on underused, already degraded land, the pressure to convert previously undeveloped land is reduced. Therefore differential standards for new development and redeveloped sites, as well as for different types of developed sites, may be reasonable. However, they should be crafted to minimize creation of imperviousness at the watershed scale, and still include some reasonable level of stormwater management at the site scale.

Redevelopment is the act of improving by renewing or restoring any developed property that results in the land disturbance of one acre or greater, and that has one of the following characteristics:

- Land that currently has an existing structure, such as buildings or houses, or
- Land that is currently covered with an impervious surface, such as a parking lot or roof, or
- Land that is currently degraded and is covered with sand, gravel, stones, or other non-vegetative covering.

Infiltration may not be appropriate in all cases. For example, a site that is a potential hot spot with the reasonable potential for significant pollutant loading(s) may not be appropriate for stormwater infiltration. Hot spots may include commercial, industrial, institutional, municipal, or transportation related operations that may produce higher levels of stormwater pollutants, and/or present a higher level or risk for spills, leaks, or illicit discharges such as: gas stations, petroleum wholesalers, vehicle maintenance and repair, auto recyclers, recycling centers and scrap yards, landfills, solid waste facilities, wastewater treatment plants, airports, railroad stations and associated maintenance facilities, and highway maintenance facilities.

In addition, the permit writer may want to consider what type of flexibility to afford sites where the owner/operator is not able to meet the performance standard on site. For instance, if a site is constrained by size or previous impervious surfaces, such that the use of control measures that infiltrate stormwater is severely limited, the permit could allow alternatives for meeting the performance standard in other ways such as payment in lieu and off-site mitigation within the same watershed.

Off-site mitigation and payment in lieu programs are options that can be used in these instances. Off-site mitigation generally means that control measures may be implemented at another location, in the same sewer/watershed as the original project, and as approved by the regulatory agency. Payment in lieu programs generally mean that the developer pays a fee to the permittee which will then be applied to a stormwater control project, in lieu of installing the required control measures.

If the permit writer chooses to include an off-site mitigation or payment in lieu program in the permit, the permit writer could specify that the programs meet several criteria, for example, those described in the 2009 West Virginia Phase II General Permit Fact Sheet (www.dep.wv.gov/WWE/Programs/stormwater/MS4/permits/Pages/default.aspx):

1. The permittee must establish clear and stringent criteria for the conditions under which these options are available that must be related to real physical constraints such as a combination of soils limiting infiltration opportunities, space or light limited situations restricting the amount of vegetation that can be used, and a land use that is not conducive to capture and use of

MS4 Permit Improvement Guide

stormwater. While one or two of these characteristics should not be adequate to qualify for the alternative, the combination of multiple constraints could;

2. A minimal requirement for at least [0.4 inch] of stormwater managed on-site;
3. A [1:1.5 ratio] of the amount of requisite stormwater not managed on-site to the amount of stormwater required to be mitigated at another site, or for which in-lieu payments must be made;
4. If demonstrated to the permittee that it is completely infeasible to manage the remainder [0.4 inches], then the ratio for this unmanaged portion is [1:2].
5. The necessary tracking systems for both types of programs, including the necessary inventory of public and retrofit projects for off-site mitigation; and,
6. The establishment of a credible valuation structure for payment in lieu, i.e., what is the actual cost for the permittee to provide retrofits for the necessary amount of stormwater, not just a token payment. The purpose of these provisions is to disincentivize the use of alternatives unless really needed, but also to provide a financial foundation for implementation of public stormwater management projects, including retrofits where those needs have been identified.

Additional justification for the development types which qualify for these incentives can be seen in the West Virginia Phase II MS4 Permit Fact Sheet

(www.dep.wv.gov/WWE/Programs/stormwater/MS4/permits/Pages/default.aspx).

5.3 Site Plan Review

Example Permit Provision

- 5.3.1 To ensure that all applicable new development and redeveloped sites conform to the performance standards required in Part 5.2, the permittee must continue to implement project review, approval, and enforcement procedures that include:
 - a. Procedures for the site plan review and approval process(es) that include inter-departmental consultations, as needed, and a required re-approval process when changes to an approved plan are desired; and
 - b. A requirement for submittal of 'as-built' certifications within 90 days of completion of a project.
- 5.3.2 The permittee must conduct site plan reviews, using the procedures described in Part 5.3.1, of all new development and redeveloped sites which will disturb greater than or equal to one acre [or a smaller threshold as set by the permitting authority] and discharge to the MS4 (including sites that disturb less than one acre that are part of a larger common plan of development or sale). The site plan review must specifically address how the project applicant meets the performance standards in Part 5.2 and how the project will ensure long-term maintenance as required in Part 5.4.

Example Permit Requirement Rationale for the Fact Sheet

Specific standards are a critical component of a stormwater management program. However, even the best requirements need to be supported by a review program to ensure that the standards are met. The example permit provision would require permittees to fully implement a comprehensive site plan review and approval program. To meet this requirement, the permittee must have the authority to withhold approvals when standards are not met.

Recommendations for the Permit Writer

The permit writer may want to consider adding a requirement for a pre-application concept plan meeting to occur (in addition to the requirement for the project applicant to submit a site plan for review). During this meeting the project land owner or developer, the project design engineer, and municipal planning staff could discuss the conceptual designs that would be used to ensure that they meet the performance standards. This meeting would ensure that stormwater and performance standards are addressed early in the development process. However, if this pre-application concept plan meeting is not consistent with local planning procedures, the permit writer could consider omitting this requirement.

5.4 Long-Term Maintenance of Post-Construction Stormwater Control Measures

Example Permit Provision

- 5.4-1 All structural stormwater control measures installed and implemented to meet the performance standards of Part 5.2 must be maintained in perpetuity. The permittee must ensure the long-term maintenance of structural stormwater control measures installed according to this Part through one, or both, of the following approaches:
- a. Maintenance performed by the Permittee. See part 6.4.
 - b. Maintenance performed by the owner or operator of a new development or redeveloped site under a maintenance agreement. The permittee must require the owner or operator of any new development or redeveloped site subject to the performance standards in Part 5.2 to develop and implement a maintenance agreement addressing maintenance requirements for any structural control measures installed on site to meet the performance standards. The agreement must allow the permittee, or its designee, to conduct inspections of the structural stormwater control measures and also account for transfer of responsibility in leases and/or deeds. The agreement must also allow the permittee, or its designee, to perform necessary maintenance or corrective actions neglected by the property owner/operator, and bill or recoup costs from the property owner/operator when the owner/operator has not performed the necessary maintenance within thirty (30) days of notification by the permittee or its designee.

MS4 Permit Improvement Guide

5.4.2 Verification of maintenance responsibilities. The permittee must require that property owners or operators of any new development or redeveloped site subject to the performance standards in Part 5.2 provide verification of maintenance for the approved structural stormwater control measures used to comply with the performance standards. Verification must include one or more of the following as applicable:

- a. The owner/operator's signed statement accepting responsibility for maintenance with a provision for transferring maintenance responsibility if the property is legally transferred to another party; and/or
- b. Written conditions in the sales or lease agreement that require the recipient to assume responsibility for maintenance; and/or
- c. Written conditions in project conditions, covenants and restrictions for residential properties assigning maintenance responsibilities to a home owner's association, or other appropriate group, for maintenance of structural and treatment control stormwater management practices; and/or
- d. Any other legally enforceable agreement that assigns permanent responsibility for maintenance of structural or treatment control stormwater management practices.

Example Permit Requirement Rationale for the Fact Sheet

Appropriate operation and maintenance are critical aspects to the function of any suite of controls. In many cases, controls may be located on private property, and it is necessary to establish some provision to assure responsibility and accountability for the operation and maintenance of these controls.

The permittee must ensure maintenance of all structural stormwater control measures. In this Guide, structural controls also include many green infrastructure practices such as rainwater harvesting, rain gardens, permeable pavement, and vegetated swales.

Recommendations for the Permit Writer

Most non-traditional MS4 permittees will probably not have the legal authority to recoup costs where the owner/operator has not completed necessary maintenance. Permit writers may want to be more specific in this requirement to include other options for non-traditional MS4 permittees.

5.5 Watershed Protection

Example Permit Provision

5.5.1 When the Permittee revises its General Plan (or equivalent) or other relevant plans (e.g. Transportation Master, or Community Plan) they must include effective water

MS4 Permit Improvement Guide

quality and watershed protection elements that require implementation of consistent water quality protection measures for new development and redeveloped sites within *[insert deadline]*. Examples of water quality and watershed protection elements to be considered include the following: *[insert principles and/or policies which are appropriate for the watershed such as,*

- Minimize the amount of impervious surfaces (roads, parking lots, roofs, etc.) within each watershed, by minimizing the creation, extension and widening of parking lots, roads and associated development.
- Preserve, protect, create and restore ecologically sensitive areas that provide water quality benefits and serve critical watershed functions. These areas may include, but are not limited to; riparian corridors, headwaters, floodplains and wetlands.
- Implement management practices that prevent or reduce thermal impacts to streams, including requiring vegetated buffers along waterways, and disconnecting discharges to surface waters from impervious surfaces such as parking lots.
- Prevent disturbances of natural waterbodies and natural drainage systems caused by development, including roads, highways, and bridges.
- Avoid development in areas that are particularly susceptible to erosion and sediment loss.
- Implement standards to protect trees, and other vegetation with important evapotranspirative qualities.
- Implement policies to protect native soils, prevent topsoil stripping, and prevent compaction of soils.
- Implement water conservation policies that will reduce both stormwater and non- stormwater discharges via storm sewer systems.²⁰
- Implement policies that encourage stormwater practices close to the source of the runoff rather than downstream and lower in the watershed.]

Example Permit Requirement Rationale for the Fact Sheet

Imperviousness has been shown to correlate with water quality impacts. In order to minimize water quality impacts, the permittee must examine their planning principles to manage the creation of impervious surfaces at the watershed level, such as reducing the footprint of streets and parking lots. Also, ecologically sensitive areas can protect water quality by acting both as filters that reduce pollutants in stormwater discharges and as sponges to reduce the impact on the ecosystem's hydrology. Thermal pollution is also a concern that can impact biota in waterways. Stormwater discharges from impervious surfaces are often characterized by higher temperatures than natural, pervious surfaces. Reducing the chances of further increasing this temperature by preserving, protecting, and restoring natural features that provide shading for the waterway can further help reduce thermal pollution. Whenever possible natural waterways

²⁰ West Virginia Small MS4 Permit (www.wvdep.org/Docs/17444_SW_WV%20MS4%20permit%202009.pdf)

MS4 Permit Improvement Guide

must be protected and not disturbed by stormwater from developed sites. For example, areas that have a high potential for erosion must be avoided for development when possible. Protecting vegetation, native soils, and conserving water can also help ensure the hydrologic qualities of the site remain intact.

Consideration of stormwater impacts from development is critical during the planning phases of development. This not only includes planning on the site-level, but also with respect to discharges from the MS4 on the watershed level. To the extent possible, stormwater management must be an integral part of higher level planning documents that determine where and how development that will result in stormwater discharges to the MS4 should occur since these decisions affect water quality. Using land efficiently can result in better stormwater management by putting development where it is most appropriate. For example, by directing and concentrating new development in areas targeted for growth, communities can reduce or remove development pressure on undeveloped parcels and protect sensitive natural lands and recharge areas. Another strategy is redeveloping already degraded sites such as abandoned shopping centers or underutilized parking lots. In this case, the net increase in discharges from developed sites would likely be zero, and it would likely decrease, depending on the on-site infiltration practices used. Also, by allowing or encouraging denser development, less land is converted overall, and less total impervious area created.

Recommendations for the Permit Writer

Examining stormwater on a watershed basis and including watershed principles is an important part of protecting waterways in a holistic manner. Climate change may increase the size and frequency of storms in some area of the nation. Including watershed-type assessments and considerations as Permit Requirements will help the permittee better focus their efforts to ensure the best water protection outcomes for existing conditions and those anticipated future conditions. Therefore, permit writers should consider including watershed protection principles. Newer programs may not be ready for permit writers to include the exact example permit provision provided. If possible, permit writers should be as specific as possible for the needs of the watershed where the MS4 permittee is located. Permittees should be careful when installing new stormwater BMPs to ensure that there are not any negative, unintended consequences.

5.6 Tracking of Post-Construction Stormwater Control Measures

Example Permit Provision

5.6.1 Inventory of Post-Construction Stormwater Control Measures. The permittee must continue to maintain an inventory of all post-construction structural stormwater control measures installed and implemented at new development and redeveloped sites, including both public and private sector sites located within the permit area. The inventory must be searchable by property location (either on paper or electronic). New entries to the inventory must be made during the site plan review and approval process in Part 5.3.1.

5.6.2 Tracking Information. Each entry to the inventory must include basic information on each project, such as project name, owner's name and contact information, location, start/end date, etc. In addition, inventory entries must include the following for each project:

- a. Short description of each stormwater control measure (type, number, design or performance specifications);
- b. Latitude and longitude coordinates of each stormwater control measure;
- c. Short description of maintenance requirements (frequency of required maintenance and inspections); and
- d. Inspection information (date, findings, follow up activities, prioritization of follow-up activities, compliance status).

Based on inspections conducted under Part 5.7, the permittee must update the inventory as appropriate where changes occur in property ownership or the specific control measures implemented at the site. This inventory must be maintained and available for review by the permitting authority.

Example Permit Requirement Rationale for the Fact Sheet

Creating an inventory of post-construction structural stormwater control measures, including tracking of specific information, will first enable permittees to know what control measures they are responsible for. Without this information the permittee will not be protecting water quality to their full potential since inspections, maintenance, and follow-up changes cannot be performed. Tracking information such as the latitude/longitude, maintenance and inspection requirements and follow-up will allow the permittee to be able to better allocate their resources for those activities that are immediately necessary. Although not required, including photographs will help the permittee assess how the control measure has changed since it was first created and will likely aid in determining proper maintenance and/or retrofitting opportunities if the measure is no longer providing the water quality benefits it was originally designed.

Recommendations for the Permit Writer

- Permit writers may wish to specifically define the types of structural controls that must be included in the inventory. For example, rain barrels may be considered a structural control, but the MS4 likely does not need latitude and longitude coordinates of the rain barrels.
-

5.7 Inspections and Enforcement

Example Permit Provision

- 5.7.1 Inspection Frequency. To ensure that all stormwater control measures are operating correctly and are being maintained as required consistent with its applicable maintenance agreement, the permittee must conduct inspections of each project site covered under Part 5.2 performance standards, *[insert inspection frequency, e.g., at least one time during the permit term, 20% of sites per year, etc.]*. The inspections must be in accordance with those specified in the *[insert State manual that describes the maintenance of control measures]*. A description of inspection procedures must be included in the SWMP document.
- 5.7.2 Post-Construction Inspection. Within *[insert deadline, e.g., 1 week, 2 weeks, etc.]* of completion of construction of any project required to meet the Section 5.2 performance standards, the permittee must conduct a post-construction inspection to verify that the permittee's performance standards have been met. The permittee must include in its SWMP a procedure for being notified by construction operators/owners of their completion of active construction so that the post-construction inspection may be conducted.
- 5.7.3 Inspection Reports. The permittee must document its inspection findings in an inspection report. Each inspection report must include:
- Inspection date;
 - Name and signature of inspector;
 - Project location (street address, latitude/longitude, etc.) and inventory reference number (from inventory established in Section 5.6.1)
 - Current ownership information (for example, name, address, phone number, fax, and email)
 - A description of the condition of the structural stormwater control measure including the quality of: vegetation and soils; inlet and outlet channels and structures; embankments, slopes, and safety benches; catch basins; spillways, weirs, and other control structures; and sediment and debris accumulation in storage and forebay areas as well as in and around inlet and outlet structures;
 - Photographic documentation of all critical structural stormwater control measure components; and

- g. Specific maintenance issues or violations found that need to be corrected by the property owner or operator along with deadlines and reinspection dates.

The permittee must document and maintain records of inspection findings and enforcement actions and make them available for review by the permitting authority.

Example Permit Requirement Rationale for the Fact Sheet

Inspection of post-construction control measures is key to ensuring the protection of water quality. If control measures are not inspected and maintained they could become sources of pollution rather than reducing pollution. By including detailed information in the inspection report, the permittee can better determine if maintenance is required and the permittee can have a snapshot of sorts to know the status of their control measures to prioritize funding.

Recommendations for the Permit Writer

Permit writers should clearly specify the requirements for inspections. Inspecting and properly maintaining structural stormwater controls to ensure they are working as designed is just as important as installing them in the first place. By having specific requirements, permittees will be reminded that they must allocate resources to ensure control measures are properly maintained and functioning. The permit writer may also want to add a prioritization scheme to the requirement to help the permittee determine what maintenance activities are priorities for protecting water quality and which ones are minor changes.

5.8 Retrofit Plan

Example Permit Provision

5.8.1 The permittee must develop a plan to retrofit existing developed sites that are impacting water quality. The retrofit plan must be developed within [*insert deadline, such as within two years of permit issuance*] and must emphasize controls that infiltrate, evapotranspire, or harvest and use stormwater discharges. The plan must include²¹:

- a. An inventory of potential retrofit locations, which considers, at a minimum:
- Locations that contribute pollutants of concern to an impaired waterbody
 - Locations that contribute to receiving waters that are significantly eroded
 - Locations that are tributary to a sensitive ecosystem or protected area
 - Locations that are tributary to areas prone to flooding

²¹ Orange County Municipal Stormwater Permit (Section F.3.d)
(www.waterboards.ca.gov/sandiego/water_issues/programs/stormwater/oc_stormwater.shtml)

MS4 Permit Improvement Guide

- b. An evaluation and ranking of the inventoried locations to prioritize retrofitting which includes, at a minimum:
- Feasibility
 - Cost effectiveness
 - Pollutant removal effectiveness
 - Impervious area potentially treated
 - Maintenance requirements
 - Landowner cooperation
 - Neighborhood acceptance
 - Aesthetic qualities, and
 - Efficacy at addressing concern.

Example Permit Requirement Rationale for the Fact Sheet

It is clear that we cannot protect the nation's waters without also addressing degradation caused by stormwater discharges from existing developed sites. For that reason stormwater programs must include substantive retrofit provisions.

It is possible and reasonable to significantly improve water quality in many urban receiving waters. This requires more than just a new development and redeveloped sites program, however, which at best can only hold the line. To actually improve the quality of receiving waters it is necessary to mitigate discharges from existing developed sites, which generally means implementation of measures to bring about the retrofit the stormwater control measures at existing sites to retain most stormwater on site.

In addition, research indicates that most streambank restoration projects that actively stabilize eroding channels should not be implemented until after hydrologic retrofits have been completed that restore the hydrologic regime not concurrently with the implementation of the retrofits.

Municipal projects, such as traffic calming sites could also include stormwater retrofit components, such as curb bump outs that include bioretention features, rain gardens, and curb cuts.

Information on retrofit options and the development of a retrofit plan can be found in the Center for Watershed Protection's guidance on Urban Stormwater Retrofit Practices (available at www.cwp.org as Manual No. 3 under the Urban Subwatershed Restoration Manual Series).

Recommendations for the Permit Writer

Permittees may need a permit term or two to adequately develop and implement a retrofit plan. Some permittees may not be ready to have retrofit plans as part of their requirements. It is up to the permit writer to make this determination based on the specific information they have available on current programs. A retrofit plan should assess the areas where retrofitting is appropriate and will result in increased water quality protection and restoration. The permit writer should determine

MS4 Permit Improvement Guide

the appropriate timeframe and language for a retrofit plan. For example, if the permittee was already required to develop a retrofit plan in a previous permit term the permit may specify a schedule for implementation rather than development.

CHAPTER 6: POLLUTION PREVENTION/GOOD HOUSEKEEPING

Introduction

Federal stormwater regulations (see 40 CFR 122.34(b)(6) and 40 CFR 122.26(d)(2)(iv)(A)) require the operator of a regulated MS4 community to develop a program to:

- Prevent or reduce the amount of stormwater pollution generated by municipal operations and conveyed into receiving waters.
- Train employees on how to incorporate pollution prevention/good housekeeping techniques into municipal operations.
- Identify appropriate control measures and measurable goals for preventing or reducing the amount of stormwater pollution generated by municipal operations.

The first step for the permittee is to evaluate and assess the areas and municipal facilities that it controls in order to determine which activities may currently have a negative impact on water quality and to find solutions for these activities. The simplest solution is to limit the number of activities that are conducted outside and exposed to stormwater.

Storm sewer systems need maintenance to ensure that structures within the storm sewer that are meant to reduce pollutants do not become sources of pollution. Regularly maintaining catch basins and cleaning storm sewer pipes prevent the accumulation of pollutants that are later released during rain events as well as blockages, backups, and flooding. Most permittees have an existing program to maintain the storm sewer infrastructure. EPA notes, however, that some of these programs have tended to focus on flood avoidance and complaint response rather than reducing water quality impacts from stormwater discharges.

The MS4 permit must require that the system be maintained to prevent the discharge of pollutants into receiving waters. System mapping and a schedule of regular maintenance are key to a successful pollution prevention program. EPA recommends establishing a tiered maintenance schedule for the entire storm sewer system area, with the highest priority areas being maintained at the greatest frequency. Priorities should be driven by water quality concerns and can be based on the land use within the MS4 area, the condition of the receiving water, the amount and type of material that typically accumulates in an area, or other location-specific factors. It is also advisable to use spill and illicit discharge data to track areas that may require immediate sewer infrastructure maintenance. It is also important for material that is collected to be disposed of in a responsible manner.

Included Concepts

- ▶ Municipal facility and control inventory
- ▶ Facility assessment
- ▶ Development of facility-specific stormwater management SOPs and Implementation of facility stormwater controls
- ▶ Storm sewer system maintenance activities
- ▶ Flood management
- ▶ Pesticide, herbicide, and fertilizer application and management
- ▶ Training and education
- ▶ Contractor requirements and oversight

MS4 Permit Improvement Guide

The procedures for storm sewer system operation and maintenance must be documented in the permittee's SOPs or similar type of documents, which are part of the permittee's SWMP. Employee training to carry out these pollution prevention measures is a required component of the program. The pollution prevention/good housekeeping/maintenance activities should be documented and, where possible, quantified (e.g., number and location of inspections and clean-outs, type and quantity of materials removed). Having permittees characterize the quantity, location, and composition of pollutants removed from catch basins can provide useful data that can later be used to assess the program's overall effectiveness, identify illicit discharges, and help the permittee better prioritize implementation activities in the future.

Specific pollution prevention requirements related to pollutant-generating activities such as landscaping techniques (including the application of pesticides, herbicides, and fertilizer) and operating and maintaining public streets, should also be included in the permit where applicable. For example, typical pollutants associated with street repair and maintenance include heavy metals, chlorides, hydrocarbons (e.g., benzene, toluene, ethylbenzene, xylene), concrete dust, sand, deicers, sediment, and trash. The permitting authority should consider requiring alternative landscaping practices such as integrated pest management (IPM), xeriscaping, or mechanical (non-chemical) removal of unwanted plants. Other landscaping controls, such as mulch management, chemical storage, reduction of soil compaction, and erosion control, should also be considered. Training and educating municipal and contracted staff is also important to ensure that everyone is knowledgeable and proficient in the newest and most effective approaches to minimizing pollutant discharges from municipal facilities and activities.

Additionally, permits should require that water quality be considered when designing flood management projects, and that existing structural flood control devices are evaluated to determine if retrofitting the device to remove/reduce pollutants from stormwater is necessary and practicable.

6.1 Municipal Facility and Control Inventory

Example Permit Provision

6.1.1 Development of a Municipal Facility and Stormwater Control Inventory – The permittee must continue to update and maintain an inventory of municipally-owned or operated facilities and stormwater controls, including but not limited to the following:

- Composting facilities
- Equipment storage and maintenance facilities
- Fuel farms
- Hazardous waste disposal facilities
- Hazardous waste handling and transfer facilities
- Incinerators
- Landfills
- Landscape maintenance on municipal property
- Materials storage yards

MS4 Permit Improvement Guide

- Pesticide storage facilities
- Public buildings, including schools, libraries, police stations, fire stations, municipal buildings, and similar buildings
- Public parking lots
- Public golf courses
- Public swimming pools
- Public works yards
- Recycling facilities
- Salt storage facilities
- Solid waste handling and transfer facilities
- Street repair and maintenance sites
- Vehicle storage and maintenance yards
- Municipally-owned and/or maintained structural stormwater controls

6.1.2 Documentation— The list of municipally-owned or operated facilities and stormwater controls must be maintained and available for review by the permitting authority.

6.1.3 Mapping – On a map of the area covered by the MS4 permit, the permittee must identify where the municipally-owned or operated facilities and stormwater controls are located. The map must identify the stormwater outfalls corresponding to each of the facilities as well as the receiving waters to which these facilities discharge. The permittee must also identify the manager of each facility and their contact information. The map must be maintained and updated regularly and be available for review by the permitting authority.

Example Permit Requirement Rationale for the Fact Sheet

Municipally-owned or operated facilities serve as hubs of activity for a variety of municipal staff from many different departments. Some municipalities will have one property at which all activities take place (e.g., the municipal maintenance yard), whereas others will have several specialized facilities such as those listed above. A comprehensive list and map of such facilities will help staff responsible for stormwater compliance build a better awareness of their locations within the MS4 service area and their potential to contribute stormwater pollutants. The facility inventory will also serve as a basis for setting up periodic facility assessments (see Part 6.2) and developing, where necessary, facility stormwater pollution prevention plans (see Part 6.3).

Recommendations for the Permit Writer

Permit writers should tailor the facilities listed in the assessment as best they can to include the facilities most likely to be owned or operated by the permittee. It is highly likely that some of the facilities listed in the Permit Requirement would not apply to most non-traditional and/or non-municipal MS4s.

6.2 Facility Assessment

Permit Requirement

6.2.1 Municipally-owned or operated facility assessment:

- a. Comprehensive Assessment of Pollutant Discharge Potential –The permittee must review, reassess, and update the comprehensive assessment of all municipally-owned or operated facilities identified in Part 6.1 [*insert frequency, e.g., annually*] for their potential to discharge in stormwater the following typical urban pollutants: sediment, nutrients, metals, hydrocarbons (e.g., benzene, toluene, ethylbenzene and xylene), pesticides, chlorides, and trash. Other pollutants may be associated with, but not generated directly from, the municipally-owned or operated facilities, such as bacteria, chlorine, organic matter, etc. Therefore, the permittee must determine additional pollutants associated with its facilities that could be found in stormwater discharges. A description of the assessment process must be included in the SWMP document.
- b. Identification of “High Priority” Facilities – Based on the Part 6.2.1.a comprehensive assessment, the permittee must identify as “high-priority” those facilities that have a high potential to generate stormwater pollutants. Among the factors that must be considered in giving a facility a high priority ranking is the amount of urban pollutants stored at the site, the identification of improperly stored materials, activities that must not be performed outside (e.g., changing automotive fluids, vehicle washing), proximity to waterbodies, poor housekeeping practices, and discharge of pollutant(s) of concern to impaired water(s). High priority facilities must include the permittee’s maintenance yards, hazardous waste facilities, fuel storage locations, and any other facilities at which chemicals or other materials have a high potential to be discharged in stormwater.
- c. Documentation of Comprehensive Assessment Results – The permittee must document the results of the assessments and maintain copies of all site evaluation checklists used to conduct the comprehensive assessment. The documentation must include the results of the permittee’s initial assessment, any identified deficiencies and corrective actions taken, and a list of the “high priority” facilities identified per Part 6.2.1.b.

Example Permit Requirement Rationale for the Fact Sheet

The initial (“first time”) comprehensive assessment is necessary to identify which of the municipality’s facilities are most likely to contribute stormwater pollutants and which are in need of stormwater controls. The assessments will involve a detailed site inspection that can identify improperly stored materials, activities that should not be performed outside (e.g., changing automotive fluids, vehicle washing), and poor housekeeping practices.

Recommendations for the Permit Writer

If the permitting authority has an established site inspection protocol to be used in the comprehensive assessment, it should be included and referenced here. The list of pollutants in this section should be modified or expanded based on pollutants of concern in the permitting authority's jurisdiction.

6.3 Development of Facility-Specific Stormwater Management SOPs and Implementation of Facility Stormwater Controls

Example Permit Provision

6.3.1 Facility-specific Stormwater Management SOPs for "High Priority" Facilities:

- a. For each "high priority" facility or operation identified in Part 6.2, the permittee must develop a site-specific SOP that identifies stormwater controls (i.e., structural and non-structural controls, and operational improvements) to be installed, implemented, and maintained to minimize the discharge of pollutants in stormwater. At a minimum, the facility-specific SOP must include the stormwater control measures described below in Part 6.3.2, as well as inspection and visual monitoring procedures and schedules described in Part 6.3.3.
- b. A copy of the facility-specific stormwater management SOP must be maintained and be available for review by the permitting authority. The SOP must be kept on-site at each of the municipally-owned or operated facilities' offices for which it was completed. The SOP must be updated as necessary.
- c. The permittee must install, implement, and maintain all stormwater controls required per Part 6.3.2 of this permit and included in the facility's site-specific SOP.

6.3.2 Stormwater Controls for "High Priority" Facilities – The following stormwater controls must be implemented at all "high priority" municipally-owned or operated facilities identified in Part 6.2. A description of any controls included in this part and any standard operating procedures developed to comply with this part must be included as part of the of each facility's SOP:

- a. General good housekeeping – The following good housekeeping practices must be implemented for all facilities identified as "high priority":
 1. The permittee must keep all municipally-owned or operated facilities neat and orderly, minimizing pollutant sources through good housekeeping procedures and proper storage of materials.
 2. Materials exposed to stormwater must be covered where feasible (without creating additional impervious surfaces, if possible).
- b. De-icing material storage – The permittee must store salt and other de-icing materials in a permanent storage structure, unless stormwater runoff from the storage piles is not discharged, or if discharges from the piles are authorized under another stormwater permit. If a permanent storage structure is required but does not exist, one must be built within *[insert timeframe]*, and seasonal

MS4 Permit Improvement Guide

tarping must be used as an interim control measure until the permanent structure is completed. If a permanent storage facility is not feasible, the permittee must provide a rationale to the permitting authority as to why and what alternate BMPs will be utilized instead.

Where a permanent storage structure is present, the permittee must perform regular maintenance and inspections of the permanent storage structure.

- c. Fueling operations – The permittee must continue to implement standard operating procedures for vehicle fueling and receiving of bulk fuel deliveries at municipally-owned or operated facilities with the goal of reducing the likelihood of spills, and providing spill controls in the event that accidental spills do occur.
- d. Vehicle maintenance – The permittee must continue to implement a standard operating procedure for vehicle maintenance and repair activities that occur at municipally-owned or operated facilities with the goal of reducing the likelihood of spills or releases and providing controls in the event that accidental spills do occur. The standard operating procedures must include regular inspections of all maintenance areas and activities.
- e. Equipment and vehicle washing – The discharge of equipment and vehicle wash wastewater to the MS4 or directly to receiving waters from municipal facilities is prohibited. The permittee may meet this requirement by either installing a vehicle wash reclaim system, capturing and hauling the wastewater for proper disposal, connecting to sanitary sewer (where applicable and approved by local authorities), ceasing the activity, and/or applying for and obtaining a separate stormwater permit.²²

6.3.3 Inspections and Visual Monitoring:

- a. Weekly visual inspections – The permittee must perform weekly visual inspections to ensure materials and equipment are clean and orderly, and to minimize the potential for pollutant discharge. The permittee must look for evidence of spills and immediately clean them up to prevent contact with precipitation or runoff. The weekly inspections must be tracked in a log for every facility, and records kept with the SWMP document. The inspection report must also include any identified deficiencies and the corrective actions taken to fix the deficiencies.
- b. Quarterly comprehensive inspections – At least once per quarter, a comprehensive inspection of “high priority” facilities, including all stormwater controls, must be performed, with specific attention paid to waste storage areas, dumpsters, vehicle and equipment maintenance/fueling areas, material handling areas, and similar potential pollutant-generating areas. The quarterly inspection results must be documented and records kept with the SOP document. This inspection must be done in accordance with the developed SOPs. The inspection report must also include any identified deficiencies and the corrective actions taken to fix the deficiencies.

²² New Jersey Tier A Phase II MS4 Permit (NJ0141852) (www.state.nj.us/dep/dwg/pdf/Tier_A_final.pdf)

- c. Quarterly visual observation of stormwater discharges – At least once per quarter, the permittee must visually observe the quality of the stormwater discharges from the “high priority” facilities (unless climate conditions preclude doing so, in which case the permittee must attempt to evaluate the discharges four times during the wet season). Any observed problems (e.g., color, foam, sheen, turbidity) that can be associated with pollutant sources or controls must be remedied within three days or before the next storm event, whichever is sooner. Visual observations must be documented, and records kept with the SOP document. This inspection must be done in accordance with the developed SOPs. The inspection report must also include any identified deficiencies and the corrective actions taken to fix the deficiencies.

Example Permit Requirement Rationale for the Fact Sheet

Each municipal facility will require a different set of control measures depending on the nature of activities that occur there and the types of materials that are stored and used. Developing and maintaining a site-specific SOP for each facility will help to ensure that employees responsible for facility operation are aware of the stormwater controls required for the site.

There are a number of storage areas and activities that are common at municipal facilities that have a high potential for polluting stormwater:

- Deicing materials, particularly road salt, are easily liberated and transported by rainfall, and constituents such as chloride are not removed by most stormwater controls.
- Fueling and vehicle maintenance and storage areas are prone to spills and drips of various automotive fluids.
- Equipment and vehicle washing areas are designed to mix water with dirt and hydrocarbons, requiring special treatment of the wastewater (including pretreatment and diversion to the sanitary sewer, if allowed) and protection of wash areas from rainfall and runoff.

The best way to avoid pollutant discharges from these sources is to keep precipitation and runoff from coming into contact with stored chemicals and activity areas that use chemicals and materials, which can become sources of stormwater pollutants. For example, the permittee must cover stockpiles, create dedicated structures for stored materials, build berms around areas of pavement to prevent clean runoff from contacting contaminated areas, and maintain a minimum distance between stockpiles and stormwater infrastructure and receiving waters. These are just a few of the ways in which these potential pollutant sources can be protected from precipitation and runoff.

The permit requires that comprehensive site inspections be conducted quarterly, which is an appropriate frequency to ensure that material stockpiles that might be moved or utilized on a seasonal basis are protected from precipitation and runoff. Also, quarterly inspections will allow inspectors to observe different types of operations that occur at different times of the year (e.g., landscape maintenance crews are less active in the winter). Quarterly visual observations are required so that inspectors can see in real time the qualitative nature of the

MS4 Permit Improvement Guide

stormwater discharge and so that corrective action can be taken where necessary to improve on-site stormwater controls.

The permit also specifies that inspection procedures, results, and controls for each facility be documented to ensure that the site inspections are consistent and that maintenance of stormwater controls remains part of the municipality's standard operating procedures. The requirement for an inspection log will allow the permitting authority to verify that periodic site inspections have been performed.

Recommendations for the Permit Writer

Neither Phase I nor Phase II regulations specifically require that MS4 permittees develop facility-specific stormwater management SOPs. However, both Phase I and Phase II require that permittees prevent or reduce pollutant discharge in stormwater from municipal facilities and activities. Requiring permittees to assess high priority facilities and develop appropriate controls for each is an effective way of requiring permittees to address potential sources of pollutants at facilities.

When setting frequency for facility inspections (see Part 6.3.3), the permit writer should consider the number of facilities and the size/complexity of the sites to ensure that enough time is available to complete the assessments.

The list of specific stormwater controls for municipal facilities will vary from place to place based on local and watershed priorities and climate considerations. The permit writer should specify stormwater controls that are appropriate for the local conditions. For example, if a permittee uses satellite locations for temporary storage of deicing materials during snow events, the permit writer may want to consider options other than the permanent storage requirement if the permittee uses the piles within a certain time frame and the piles are covered by temporary tarping or a similar control.

6.4 Storm Sewer System Maintenance Activities

Example Permit Provision

6.4.1 MS4 catch basin maintenance

- a. Assessment/prioritization of catch basins – The permittee must assign a priority to each of its catch basin inlets within its jurisdiction as one of the following:
 - Priority A – Catch basins that are designated as consistently generating the highest volumes of trash and/or debris
 - Priority B – Catch basins that are designated as consistently generating moderate volumes of trash and/or debris
 - Priority C – Catch basins that are designated as generating low volumes of trash and/or debris

The permittee must use information compiled from citizen complaints/reports to help in the determination of the appropriate priority level. A description of

MS4 Permit Improvement Guide

the prioritization scheme must be included in the SWMP.

- b. Catch basin inspection and cleaning
 1. Based on the priorities assigned in Part 6.4.1.a., the permittee must inspect and clean catch basins in accordance with the following schedule:
 - Priority A – [*Insert cleanout frequency, e.g., 3 times per year*]
 - Priority B – [*Insert cleanout frequency, e.g., 2 times per year*]
 - Priority C – [*Insert cleanout frequency, e.g., 1 time per year*]The permittee must develop a catch basin cleaning schedule based on the frequency specified in this permit, along with a list of each of its catch basins and the priority assigned to them per Part 6.4.1.a.
 2. In addition to catch basin cleanings performed above, the permittee must ensure that any catch basin that is inspected and found to be between one third and one half full of trash and/or debris must be cleaned within [*Insert cleanout frequency e.g., 1 week of discovery*].²³ The permittee must maintain a log of all maintenance performed.
 3. The permittee must document that it has performed all required catch basin cleanings in a log that is to be made available for review by the permitting authority upon request.
- c. Catch basin labeling – The permittee must ensure that each catch basin includes a legible stormwater awareness message (e.g., a label, stencil, marker, or pre-cast message such as “drains to the creek” or “only rain in the drain”). Catch basins with illegible or missing labels must be recorded and re-labeled within [*insert number of days*] of inspection.
- d. Maintenance of surface drainage structures – The permittee must visually monitor permittee-owned open channels and other drainage structures for debris at least [*specify frequency, e.g., once per year*] and identify and prioritize problem areas, such as those with recurrent illegal dumping, for inspection at least [*specify frequency, e.g., three times per year*]. Removal of trash and debris from open channels and other drainage structures must occur [*insert frequency of open channel/drainage structure cleaning, e.g., annually*]. The permittee must document its drainage structure maintenance in a log that is to be made available for review by the permitting authority upon request.
- e. Disposal of waste materials – The permittee must develop a procedure to dewater and dispose of materials extracted from catch basins. This procedure must ensure that water removed during the catch basin cleaning process and waste material will not reenter the MS4.

6.4.2 Municipal activities and operations

- a. Assessment of municipal activities and operations

²³ EPA's Office of Research and Development documented a threshold sump level of ½ as a break point where solids retainage was either erratic or negative (Catchbasin Technology Overview and Assessment #EPA-600/2-77-051 1977).

MS4 Permit Improvement Guide

1. The permittee must maintain and revise as necessary the operation and maintenance (O&M) activity assessment. The following municipal O&M activities must be included in the assessment for their potential to discharge pollutants in stormwater:

- Road and parking lot maintenance, including pothole repair, pavement marking, sealing, and re-paving
- Bridge maintenance, including re-chipping, grinding, and saw cutting
- Cold weather operations, including plowing, sanding, and application of deicing compounds and maintenance of snow disposal areas
- Right-of-way maintenance, including mowing, herbicide and pesticide application, and planting vegetation
- Municipally-sponsored events such as large outdoor festivals, parades, or street fairs

2. The permittee must identify all materials that could be discharged from each of these O&M activities. Typical pollutants associated with these activities include metals, chlorides, hydrocarbons (e.g. benzene, toluene, ethylbenzene, xylene), sediment, and trash.

3. The permittee must develop a set of pollution prevention measures that, when applied during municipal O&M activities, will reduce the discharge of pollutants in stormwater. These pollution prevention measures must include, at a minimum:

- Replacing materials/chemicals with more environmentally benign materials or methods (e.g., use mechanical methods vs. herbicides, or use water-based paints or thermoplastics rather than solvent-based paints for stripping)
- Changing operations to minimize the exposure or mobilization of pollutants (e.g., mulch, compost or landfill grass clippings) to prevent them from entering surface waters
- Placing barriers around or conducting runoff away from deicing chemical storage areas to prevent discharge into surface waters), consistent with Part 6.3.2.b

[If available in your particular State or the municipality, insert relevant section of SWMP, or other relevant document, that includes specific stormwater controls that must be used.]

4. The permittee must develop and implement a schedule for instituting the pollution prevention measures. At a minimum, with respect to all roads, highways, and parking lots with more than 5,000 square feet of pollutant-generating impervious surface area that are owned, operated, or maintained, the permittee must implement all pollution prevention measures by *[insert deadline]*.

5. The results of the assessments and pollution prevention measures, including schedules for implementation, must be documented and made available for review by the permitting authority upon request.

MS4 Permit Improvement Guide

- b. Inspection of pollution prevention measures – All pollution prevention measures implemented at municipal facilities must be visually inspected [*insert frequency, e.g., monthly or quarterly*] to ensure they are working properly; a log of inspections must be maintained and made available for review by the permitting authority upon request.

6.4.3 Street Sweeping and Cleaning

- a. The permittee must continue to evaluate and rate all municipally-owned streets, roads, and public parking lots within their jurisdiction. The permittee must include in the evaluation the sweeping frequency, timing, and efficiency of existing street sweeping programs. The street sweeping frequency must be based on land use, trash and stormwater pollutant levels generated. At a minimum, the following areas must be regarded as “high priority,” for sweeping activities while the “medium priority” and “low priority” areas are recommended:
- High priority – Streets, road segments, and public parking lots designated as high priority include, but are not limited to, high traffic zones, commercial and industrial districts, shopping malls, large schools, high-density residential dwellings, sport and event venues, and plazas. This designation must include areas that consistently accumulate high volumes of trash, debris, and other stormwater pollutants.
 - Medium priority – Streets, road segments and public parking lots designated as medium priority include, but are not limited to, medium traffic zones; warehouse districts; and light, small-scale commercial and industrial areas.
 - Low priority – Streets and road segments designated as low priority include, but are not limited to, light traffic zones and residential zones.
- b. The permittee must show on a map of its service area how the streets, roads, and public parking lots have been rated in accordance with Part 6.4.3.a.
- c. Implementing sweeping schedules – The permittee must sweep streets/roads/public parking lots in accordance with the following frequency:
- High priority – average of at least [*insert frequency, e.g., twice per month*]
 - Medium priority – average of at least [*insert frequency, e.g., once per month*]
 - Low priority – [*insert frequency, e.g., twice per year*]
- If a permittee’s existing overall street sweeping effort provides equivalent or greater street sweeping frequency relative to the requirements above, the permittee may continue to implement its existing street sweeping program.
- d. For areas where street sweeping is technically infeasible (e.g., streets without curbs), the permittee must increase implementation of other trash/litter control procedures to minimize pollutant discharges to storm drains and creeks. The permittee must show on its Part 6.4.3.b map the location of these areas.
- e. Sweeping equipment selection and operation
1. When replacing existing sweeping equipment, the permittee must select and operate high-performing sweepers that are efficient in removing pollutants,

MS4 Permit Improvement Guide

including fine particulates, from impervious surfaces.

2. The permittee must follow equipment design performance specifications to ensure that street sweeping equipment is operated at the proper equipment design speed with appropriate verification, and that it is properly maintained.
3. The permittee must operate sweepers to optimize pollutant removal by permitting sweepers access to the curb through the use of parking restrictions that clear the curb or through effective public outreach to inform citizens of sweeping days and times so that voluntary curb clearing can occur.
- f. Sweeper Waste Material Disposal – The permittee must develop a procedure to dewater and dispose of street sweeper waste material. This procedure must ensure that water and material will not reenter the MS4.
- g. Operator training – Street sweeper operators must be trained to enhance operations for water quality benefit.
- h. The permittee must include the following in the SWMP and update as changes are made:
 1. A description of the street sweeping frequency and any significant changes in the sweeping frequency map, along with the basis for those changes
 2. The types of sweepers used
 3. A summary of the proper sweeping operation verification results and street sweeping methods, including the way in which the permittee specifies and confirms the rate or speed at which street miles are covered by sweeper operators
 4. The use of additional resources in sweeping seasonal leaves or pick-up of other material
 5. A description of the methods for addressing areas identified in Part 6.4.3, considered infeasible for street sweeping

6.4.4 Maintenance of municipally-owned and/or maintained structural stormwater controls

- a. The permittee must inspect at least [*insert frequency, e.g., yearly*], and maintain if necessary, all municipally-owned or maintained structural stormwater controls. The permittee must also maintain all green infrastructure practices through regularly scheduled maintenance activities.

Example Permit Requirement Rationale for the Fact Sheet

MS4 Maintenance

Traditional municipal storm drain systems were designed to quickly collect and convey runoff to receiving waters. The purpose of catch basin, inlet, and storm drain cleanouts is to prevent blockages, flooding, and reduce pollution.

MS4 Permit Improvement Guide

Fine particles and pollutants from run-on, atmospheric deposition, vehicle emissions, breakup of street surface materials, littering, and sanding can accumulate along the curbs of roads in between rainfall events. This results in the accumulation of pollutants such as sediment, nutrients, metals, hydrocarbons, bacteria, pesticides, trash and other toxic chemicals. Storm drain maintenance is often the last opportunity to remove pollutants before they enter the storm-drain-system. Because they effectively trap solids, they need to be cleaned out periodically to prevent those materials from being transported by high stormwater flows. By doing so the MS4 will prevent trash and litter from ultimately becoming sources of marine debris, which is any man-made, solid material that enters waterways either directly or indirectly.

The permit includes a priority ranking approach for catch basins so that municipal resources are directed to the areas and structures that generate the most pollutants. A priority ranking system is required because some catch basins will accumulate pollutants faster than others based on the nature of the drainage area and whether controls are present upstream of the catch basin. Catch basins with the highest accumulations will need to be cleaned more often than those with low accumulations. The permit language also includes a requirement that triggers catch basin cleaning when a catch basin is one-third full.

Proper storm drain system cleanout includes vacuuming or manually removing debris from catch basins; vacuuming or flushing pipes to increase capacity and remove clogs; removing sediment, debris, and overgrown vegetation from open channels; and repairing structures to ensure the integrity of the drainage system. It is important to conduct regular inspections of all storm sewer infrastructure and perform maintenance as necessary. Though these activities are intended to ensure that the sewer system is properly maintained and that any accumulated pollutants are removed prior to discharge, if not properly executed, cleanout activities can result in pollutant discharges. In selecting maintenance practices, the permittee must carefully evaluate each with an eye towards stormwater pollution potential to minimize unintended pollutant discharges, such as the use of flushing storm drain pipes to remove debris without recapturing the debris further down the pipe.

The materials removed from catch basins may not reenter the MS4. The material must be dewatered in a contained area and the water treated with an appropriate and approved control measure or discharged to the sanitary sewer. The solid material will need to be stored and disposed of properly to avoid discharge during a storm event. Some materials removed from storm drains and open channels may require special handling and disposal, and may not be authorized to be disposed of in a landfill.

Street Sweeping and Cleaning

Street and parking lot sweeping is a practice that most municipalities initially conducted for aesthetic purposes. However, the water quality benefits are now widely recognized. Street sweeping also prevents particulate matter associated with road dust from accumulating on public streets and washing into storm drains.

The permit language addresses a number of important factors that impact the effectiveness of a street sweeping program. The first factor is the type of equipment used; the permit language stipulates that when equipment needs to be replaced, high-performance sweepers are purchased preferentially. Street sweeping has traditionally been more effective at removing large-sized particles, but new equipment has been developed to remove smaller, fine-grained particles. Mechanical sweepers (broom-type) are usually the least expensive and are better suited to pick up

MS4 Permit Improvement Guide

large-grained sediment. Vacuum and regenerative air sweepers are better at removing fine-grained sediment particles, but they are more expensive. Removal efficiency can be improved through tandem sweeping (i.e., two sweepers sweeping the same route, with one following the other to pick up missed material), or if the street sweeper makes multiple passes on a street.

The second factor influencing street sweeping effectiveness is the way in which the equipment is operated; the permit specifies that equipment be operated according to the manufacturers' operating instructions by operators who have been trained to sweep in accordance with the Permit Requirements in order to protect water quality.

The third determining factor is the degree to which parked cars block sweeper access to the curb; one of the best ways to ensure access to the curb is to establish parking restrictions based on sweeping schedules and to inform residents of the schedule so they can voluntarily move their cars. The permit requires that the permittee institute parking restrictions and/or a public outreach campaign requesting that cars be parked elsewhere to accommodate sweeping schedules.

Because not all streets are suitable for sweeping (e.g., those that don't have a curb and gutter), source controls can be used in place of sweeping in those areas.

The permittee is required to maintain documentation of sweeping events and characterize the quantity and composition of pollutants removed from roadways. Street sweeping data are relatively easy to track and maintain, so the permit includes requirements for reporting and assessment of the effectiveness of the sweeping activities based on equipment used, miles swept, and the amount of materials collected.

The street sweeping material may not reenter the MS4. The material must be dewatered in a contained area and the water treated with an appropriate and approved control measure or discharged to the sanitary sewer. The solid material will need to be stored and disposed of properly to avoid discharge during a storm event. Some materials may require special handling and disposal, and may not be authorized to be disposed of in a landfill.

Recommendations for the Permit Writer

MS4 Maintenance

MS4s should have a specific schedule to clean out their storm drains since it will ensure that the debris that is trapped in the system will not move into waterbodies and ultimately become marine debris in the ocean. For additional information to include on marine debris go to the EPA's Marine Debris website (www.epa.gov/owow/oceans/debris).

The frequency and timing of visual assessments and cleaning of storm drains and open channels can be tailored to local climate conditions. For example, one approach would be to require that visual observations and cleanings be conducted before the start of the wet season or before spring snowmelt.

The permitting authority should review and approve dewatering and disposal methods for materials removed from catch basins.

Catch basin labeling is believed to be an effective mechanism for educating residents since it involves a direct reminder that that water or other materials which flow into storm drains is not

MS4 Permit Improvement Guide

treated in any way, but instead drains directly to nearby waterways. There are many methods for labeling catch basins and the permit writer should work with the permittee to determine the most feasible and cost effective method of delivering the “drains to stream” message.

Street Sweeping and Cleaning

Street-sweeping frequency and timing can be based on climate conditions and seasonal variation in pollution loading. For example, in cold climates where sand is used for winter road maintenance, the permit language could specify increased sweeping during the winter and prior to the spring snowmelt. In areas with a rainy season, sweeping might be timed to occur before the rainy season starts.

In the fall, sweepers can be used to pick up leaves, as they can contribute 25 percent of nutrient loadings in catch basins. If more substantial piles of leaves are found in the community during the fall, street sweeping activities should be coordinated with leaf pick-up. Equally important is an early spring sweeping before rains begin to pick up sand, de-icing material, and winter debris. More frequent sweeping may reduce the need for catch basin cleaning.

The prioritization of sweeping activities (high, medium, low) should be based on standard categories that are based on traffic frequencies and used to determine service levels for the roadways. The example provided in the permit language is based on specific information for the location.

The permitting authority should review and approve dewatering and disposal methods for street sweeping material.

6.5 Flood Management

Example Permit Provision

6.5.1 Flood Management Projects – Within *[insert deadline, such as two years]* of permit issuance, the permittee must develop and implement a process to assess the water quality impacts in the design of all new flood management projects that are associated with the permittee or that discharge to the MS4. This process must include consideration of controls that can be used to minimize the impacts to site water quality and hydrology while still meeting the project objectives. Beginning *[insert deadline, such as three years]* from date of permit issuance, the permittee must assess at least *[insert number of projects to be evaluated, such as two]* existing flood management projects per year to determine whether changes or additions should be made to improve water quality.²⁴ A description of this process must be included in the SWMP document.

²⁴ Eastern Washington Phase II MS4 Permit (www.ecy.wa.gov/programs/wq/stormwater/municipal/phaseiiEwa/MODIFIEDpermitDOCS/EWpermitMODsigned.pdf)

MS4 Permit Improvement Guide

Example Permit Requirement Rationale for the Fact Sheet

This permit requires that existing flood management projects be prioritized and a set number be evaluated to identify opportunities for water quality retrofits. This is because the focus of stormwater management in the past had been to control flooding and mitigate property damage, with less emphasis on water quality protection. These structures may handle a significant amount of stormwater and therefore offer an opportunity to modify their design to include water quality features for less than the cost of building new controls. This requirement applies not only to new flood control projects, but also to existing structures.

6.6 Pesticide, Herbicide, and Fertilizer Application and Management

Example Permit Provision

6.6.1 Landscape maintenance

- a. The permittee must evaluate the materials used and activities performed on public spaces such as parks, schools, golf courses, easements, public rights of way, and other open spaces for pollution prevention opportunities. Maintenance activities for the turf landscaped portions of these can include mowing, fertilization, pesticide application, irrigation, etc. Typical pollutants include sediment, nutrients, hydrocarbons, pesticides, herbicides and organic debris.
- b. The permittee must implement the following practices to minimize landscaping-related pollutant generation:
 1. Educational activities, permits, certifications, and other measures for municipal applicators and distributors.
 2. Integrated pest management measures that rely on non-chemical solutions, including
 - Use of native plants, xeriscaping in arid/semi-arid regions (reduces water usage and fertilization)
 - Keeping clippings and leaves away from waterways and out of the street using mulching, composting, or landfilling
 - Limiting application of pesticides and fertilizers if precipitation is forecasted within 24 hours or as specified in label instructions
 - Limiting or replacing pesticide use (e.g., manual weed and insect removal)
 - Limiting or eliminating the use of fertilizers, or, if necessary, prohibiting application within 5 feet of pavement, 25 feet of a storm drain inlet, or 50 feet of a waterbody
 - Reducing mowing of grass to allow for greater pollutant removal, but not jeopardizing motorist safety
 3. Schedules for chemical application that minimize the discharge of such constituents due to irrigation and expected precipitation.

4. The collection and proper disposal of unused pesticides, herbicides, and fertilizers.²⁵

Example Permit Requirement Rationale for the Fact Sheet

The permit focuses on requiring source controls to reduce the amount of chemicals used. The permit specifies the use of integrated pest management, selection of native vegetation that is naturally adapted to local conditions and therefore requires fewer chemical and water inputs, reducing exposure of the chemicals to water by scheduling application according to weather forecasts and plant needs, and ensuring that municipal employees who are responsible for storing and handling these materials are educated about their use, disposal, and possible impacts.

Recommendations for the Permit Writer

EPA is currently developing a general permit to control discharges from the application of pesticides to or over, including near, waters of the U.S. EPA is working closely with state NPDES and pesticide control authorities, the regulated community, and environmental organizations to develop its permit that will be required for such discharges beginning in April 2011. It is important to note that some of the permit language in this section may need to be altered to be consistent with the pesticide permit once it is finalized. For up-to-date information, go to EPA's website (www.epa.gov/npdes/agriculture).

6.7 Training and Education

Example Permit Provision

6.7.1 Employee Training Requirements – Permittees must develop an annual employee training program for appropriate employees involved in implementing pollution prevention and good housekeeping practices in the preceding Parts. All new hires must receive training within the first year of their hire date. This annual training must include a general stormwater education component, any new technologies, operations, or responsibilities that arise during the year, and the Permit Requirements that apply to the staff being trained. A description of the program must be maintained for review by the permitting authority. The permittee must also identify and track all personnel requiring training and records must be maintained. Training must begin [*insert deadline*] from the effective date of permit authorization.

²⁵ San Diego Phase I MS4 Permit (CAS0108758) (www.swrcb.ca.gov/rwqcb9/water_issues/programs/stormwater/docs/oc_permit/updates_8_13_09/R9-2009-0002_12Aug09.pdf)

Example Permit Requirement Rationale for the Fact Sheet

The regulations found at 40 CFR 122.34(b)(6) specifically requires that the permittee develop a "training component" that trains employees "to prevent and reduce stormwater pollution from activities such as park and open space maintenance, fleet and building maintenance, new construction and land disturbances, and storm water system maintenance." This permit requires employee training for existing and new employees who are involved in performing pollution prevention and good housekeeping practices. All training must include a general stormwater educational component, including an overview of the requirements with which the municipality needs to comply. The permittee is responsible for identifying which staff must attend trainings based on the applicability of the topics listed, and they are required to conduct refresher training on an annual basis.

Recommendations for the Permit Writer

The topics included in the trainings should take into consideration the types of activities in which the municipality engages and the extent to which such activities are performed in-house or contracted.

6.8 Contractor Requirements and Oversight

Example Permit Provision

6.8.1 Requirements for Contractors:

- a. Any contractors hired by the permittee to perform municipal maintenance activities must be contractually required to comply with all of the stormwater control measures, good housekeeping practices, and facility-specific stormwater management SOPs described above.
- b. The permittee must provide oversight of contractor activities to ensure that contractors are using appropriate control measures and SOPs. Oversight procedures must be described in the SWMP document.

Example Permit Requirement Rationale for the Fact Sheet

Many municipalities use third-party contractors to conduct municipal maintenance activities in lieu of using municipal employees. Contractors performing activities that can affect stormwater quality must be held to the same standards as the permittee. Not only must these expectations be defined in contracts between the permittee and its contractors, but the permittee is responsible for ensuring, through contractually-required documentation or periodic site visits, that contractors are using stormwater controls and following standard operating procedures.

CHAPTER 7: INDUSTRIAL STORMWATER SOURCES

Introduction

Phase I MS4 permittees are required to develop and implement an inspection and oversight program to monitor and control pollutants in stormwater discharges to the MS4 from industrial facilities. Regulations addressing industrial stormwater management in Phase I MS4 permits is found at 40 CFR 122.26(d)(2)(i)(B, C, E, and F) and 40 CFR 122.26(d)(2)(iv). Requirements to regulate the stormwater discharges from commercial facilities are found at 40 CFR 122.26(d)(2)(iv)(A).

This program component typically applies only to Phase I MS4 permittees as Phase II federal regulations (40 CFR 122.34(b)) do not specifically address stormwater discharges from industrial facilities and commercial businesses (other than as part of the education and outreach program). However, EPA recommends that permit writers consider including requirements pertaining to stormwater discharges to the MS4 from industrial sources in Phase II permits to further reduce stormwater pollutants from the MS4.

Phase I MS4 regulations specify that several key elements be included in Phase I MS4 stormwater management programs. These elements include: adequate legal authority to require compliance and inspect sites, inspection of priority industrial and commercial facilities, establishing control measure requirements for facilities that may pose a threat to water quality, and enforcing stormwater requirements. In order to implement these requirements, MS4 permits require the development of an inventory of facilities and prioritization protocol and adequate staff training to ensure proper inspection and enforcement of requirements.

Included Concepts

- ▶ Facility inventory
- ▶ Industrial facility stormwater control measures
- ▶ Industrial and commercial facility inspections
- ▶ Staff training

7.1 Facility Inventory

Example Permit Provision

7.1.1 Source Identification

- a. The permittee must continue to maintain an inventory of all industrial and commercial sites/sources within its jurisdiction (regardless of ownership) that could discharge pollutants in stormwater to the MS4. The inventory must be updated [*insert frequency, e.g. annually*] and available for review by the permitting authority upon request.
- b. The inventory must include the following minimum information for each industrial and commercial site/source:
 1. Name

MS4 Permit Improvement Guide

2. Address
3. Physical location of storm drain receiving discharge
4. Name of receiving water
5. Pollutants potentially generated by the site/source
6. Identification of whether the site/source is (1) tributary to an impaired water body segment (i.e., whether it is listed under Section 303(d) of the Clean Water Act) and (2) whether it generates pollutants for which the water body segment is impaired
7. A narrative description including standard industrial classification (SIC) codes, which best reflects the principal products or services provided by each facility.

The use of a geolocational database system is highly recommended.

- c. At a minimum, the following sites/sources must be included in the inventory:

1. Commercial Sites/Sources:

[insert commercial sources that are a priority such as

- Airplane repair, maintenance, fueling, or cleaning
- Animal facilities
- Automobile and other vehicle body repair or painting
- Automobile (or other vehicle) parking lots and storage facilities
- Automobile repair, maintenance, fueling, or cleaning
- Boat repair, maintenance, fueling, or cleaning
- Building material retailers and storage
- Cement mixing or cutting
- Eating or drinking establishments (e.g., restaurants), including food markets
- Equipment repair, maintenance, fueling, or cleaning
- Golf courses, parks and other recreational areas/facilities
- Landscaping
- Marinas
- Masonry
- Mobile automobile or other vehicle washing
- Mobile carpet, drape or furniture cleaning
- Nurseries and greenhouses
- Painting and coating
- Pest control services
- Pool and fountain cleaning
- Portable sanitary services

MS4 Permit Improvement Guide

- Power washing services
 - Retail or wholesale fueling]
2. Industrial Sites/Sources:
 - Industrial Facilities, as defined at 40 CFR § 122.26(b)(14), including those subject to the Multi Sector General Permit or individual NPDES permit
 - Facilities subject to Title III of the Superfund Amendments and Reauthorization Act (SARA)
 - Hazardous waste treatment, disposal, storage and recovery facilities
 3. All other commercial or industrial sites/sources tributary to an impaired water body segment, where the site/source generates pollutants for which the water body segment is impaired
 4. All other commercial or industrial sites/sources that the permittee determines may contribute a significant pollutant load to the MS4²⁶

Example Permit Requirement Rationale for the Fact Sheet

The permit requires the permittee to develop an inventory of all potential commercial and industrial sites/sources that could contribute pollutants to the MS4. A list of specific commercial and industrial sites/sources is included in the permit, and additional sites/sources can be added if they are likely to discharge a pollutant of concern to an impaired waterbody or they are contributing a significant pollutant load to the MS4.

The inventory information will provide the permittee with information on potential pollutant sources that contribute to its MS4 system, and at what locations in the system into which they discharge. This information will also allow the permittee to prioritize inspections and tailor education and outreach efforts, which will best assist the facility in implementing appropriate pollution prevention practices or other on-site stormwater controls. In addition, the inventory data will allow the permittee to determine whether the facilities may discharge pollutants of concern into impaired waters. Finally, the information contained in the inventory will enable permittees to characterize these facilities and prioritize them based on their potential impact on stormwater quality. By prioritizing facilities in such a manner, the permittee may then establish a targeted approach towards conducting inspections (see Part 7.3 for a discussion of inspection frequency).

In addition, data from NPDES pretreatment programs within the MS4 boundary on significant industrial users (SIUs) could also be used to identify and prioritize the industrial sites in the stormwater program.

²⁶San Diego MS4 Permit (www.swrcb.ca.gov/rwqcb9/water_issues/programs/stormwater/docs/sd_permit/r9_2007_0001/2007_0001final.pdf), with modifications.

Recommendations for the Permit Writer

The example permit provision lists specific commercial and industrial sources to be included in the inventory, but permit writers should customize this list to meet specific issues in their area. For example, some permittees may have large industrial areas with few commercial businesses, while others may have a large number of restaurants and retail businesses but no industrial facilities at all. Other permittees may have had past water quality problems at certain types of commercial or industrial sites, in which case such facilities should be included in their inventories.

7.2 Industrial Facility Stormwater Control Measures

Example Permit Provision

7.2.1 The permittee must require industrial and commercial facilities included in the Part 7.1 inventory to select, install, implement, and maintain stormwater control measures. At a minimum, these control measures must:

- a. Minimize Exposure – Industrial/commercial facilities must minimize the exposure of manufacturing, processing, and material storage areas (including loading and unloading, storage, disposal, cleaning, maintenance, and fueling operations) to rain, snow, snowmelt, and runoff by either locating these industrial materials and activities inside or protecting them with storm resistant coverings (although significant enlargement of impervious surface area is not recommended). The facilities must consider, where appropriate:
 1. Using grading, berming, or curbing to prevent runoff of contaminated flows and divert run-on away from these areas
 2. Locating materials, equipment, and activities so that leaks are contained in existing containment and diversion systems (confine the storage of leaky or leak-prone vehicles and equipment awaiting maintenance to protected areas)
 3. Cleaning up spills and leaks promptly using dry methods (e.g., absorbents) to prevent the discharge of pollutants
 4. Using drip pans and absorbents under or around leaky vehicles and equipment or store indoors where feasible
 5. Using spill/overflow protection equipment
 6. Draining fluids from equipment and vehicles prior to on-site storage or disposal
 7. Performing all cleaning operations indoors, under cover, or in bermed areas that prevent runoff and run-on and also that capture any overspray
 8. Ensuring that all wash water drains to a proper collection system (i.e., not the stormwater drainage system)
- b. Follow Good Housekeeping Practices – Industrial/commercial facilities must keep clean all exposed areas that are potential sources of pollutants, using such

MS4 Permit Improvement Guide

- measures as sweeping at regular intervals, keeping materials orderly and labeled, and storing materials in appropriate containers.
- c. Conduct Maintenance – Industrial/commercial facilities must regularly inspect, test, maintain, and repair all industrial equipment and systems to avoid situations that may result in leaks, spills, and other releases of pollutants in stormwater discharged to receiving waters.
 - d. Implement Spill Prevention and Response Procedures – Industrial/commercial facilities must minimize the potential for leaks, spills and other releases that may be exposed to stormwater and develop plans for effective response to such spills if or when they occur. At a minimum, the facilities must implement:
 1. Procedures for plainly labeling containers (e.g., “Used Oil,” “Spent Solvents,” “Fertilizers and Pesticides,”) that could be susceptible to spillage or leakage to encourage proper handling and facilitate rapid response if spills or leaks occur
 2. Preventative measures such as barriers between material storage and traffic areas, secondary containment provisions, and procedures for material storage and handling
 3. Procedures for expeditiously stopping, containing, and cleaning up leaks, spills, and other releases. Employees who may cause, detect, or respond to a spill or leak must be trained in these procedures and have necessary spill response equipment available.
 4. Procedures for notification of appropriate facility personnel, emergency response agencies, and regulatory agencies [*Insert appropriate contacts for reporting*]
 - e. Implement Erosion and Sediment Controls – Industrial/commercial facilities must stabilize exposed areas and contain runoff using structural and/or non-structural control measures to minimize onsite erosion and sedimentation, and the resulting discharge of pollutants.
 - f. Manage Runoff – Industrial/commercial facilities must divert, infiltrate, reuse, contain, or otherwise reduce stormwater runoff, to minimize pollutants in discharges.
 - g. Address Salt Storage Piles or Piles Containing Salt – Industrial/commercial facilities must enclose or cover storage piles of salt, or piles containing salt, used for deicing or other commercial or industrial purposes, including maintenance of paved surfaces. If a permanent storage structure is required but does not exist, one must be built within [*insert timeframe*], and seasonal tarping must be used as an interim control until the permanent structure is completed. Facilities must implement appropriate measures (e.g., good housekeeping, diversions, containment) to minimize exposure resulting from adding to or removing materials from the pile. Piles do not need to be enclosed or covered if stormwater runoff from the piles is not discharged or if discharges from the piles are authorized under another NPDES permit.
 - h. Conduct Employee Training – All facility employees who work in areas where industrial materials or activities are exposed to stormwater, or who are

MS4 Permit Improvement Guide

responsible for implementing activities necessary to manage stormwater must be trained. Training must be conducted [*insert frequency, e.g. at least annually*].

- i. Address Non-Stormwater Discharges – Industrial/commercial facilities must eliminate non-stormwater discharges not authorized by an applicable NPDES permit.
- j. Control Waste, Garbage and Floatable Debris – Facilities must ensure that waste, garbage, and floatable debris are not discharged to receiving waters by keeping exposed areas free of such materials or by intercepting them before they are discharged.
- k. Control Dust Generation and Vehicle Tracking of Industrial Materials – Industrial/commercial facilities must minimize generation of dust and off-site tracking of raw, final, or waste materials.²⁷

7.2.2 Within the [*insert deadline, e.g. first two years of permit term*], the permittee must notify the owner/operator of each industrial and commercial site/source of the stormwater requirements for control measures in Part 7.2.1.

7.2.3 As necessary to minimize any pollutants causing the applicable receiving waterbody to be listed as impaired, the permittee must require implementation of additional controls for industrial and commercial sites/sources that are tributary to the impaired water body segments and that are likely to generate such impairment pollutants.²⁸

Example Permit Requirement Rationale for the Fact Sheet

The permittee is required to ensure that the minimum control measures are implemented, as applicable, at every industrial/commercial facility included in its inventory. The minimum measures outlined, when properly selected, designed and implemented, promote prevention and source control, before treatment.

The control measures in this permit are consistent with the control measure requirements found in EPA's 2008 Multi-Sector General Permit (MSGP) for stormwater discharges from industrial activities. The permit writer should ensure that these requirements are consistent with the State's industrial stormwater permit. The control measures in this permit describe specific activities that the permittee must require industrial facilities and commercial sites to implement to minimize stormwater pollution. Another control measure is simply preventing pollutants from coming into contact with precipitation in the first place since this will ensure they are not carried into nearby waterways. General good housekeeping and maintenance procedures are also required. Additional control measures address spill prevention and response, erosion and sediment controls, managing runoff, and controlling discharges from salt storage piles.

²⁷ 2008 MSGP (Section 2) (www.epa.gov/npdes/pubs/msgp2008_finalpermit.pdf), with modifications

²⁸ San Diego MS4 Permit (www.swrcb.ca.gov/rwqcb9/water_issues/programs/stormwater/docs/sd_permit/r9_2007_0001/2007_0001final.pdf), with modifications

MS4 Permit Improvement Guide

The control measures must also include employee training, controlling non-stormwater discharges, addressing waste, garbage and floatable debris, and addressing dust generation and vehicle tracking.²⁹

The permittee is required to notify industrial and commercial sites of the control measure requirements and their responsibility to implement and comply with the requirements.

Facilities that discharge into impaired waterbodies may be required to implement additional controls as necessary to prevent the discharge of the associated pollutants of concern.

7.3 Industrial and Commercial Facility Inspections

Example Permit Provision

7.3.1 Industrial and Commercial Site Inspection Program

- a. The permittee must continue to implement a program to inspect all commercial and industrial facilities included in its Part 7.1(a) inventory. The permittee must describe how this will occur in the SWMP.
- b. The inspection program must:
 1. Prioritize all facilities into high, medium, and low categories on the basis of the potential for water quality impact using criteria such as pollutant sources on site, pollutants of concern, proximity to a water body, and violation history of the facility. The different priority categories will be assigned different inspection frequencies, with the highest priority facilities receiving more frequent inspections. Describe the process for prioritizing inspections and frequency of inspections. If any geographical areas are to be targeted for inspections due to high potential for stormwater pollution, these areas must be listed in the Inspection Plan.
 3. Explain how the priority assigned to any one facility may be modified based on the site inspection findings and the facility's potential to discharge pollutants.

7.3.2 Minimum Inspection Requirements

- a. Inspection Frequency – The permittee is required to conduct inspections at the following frequencies, at a minimum:
 1. Facilities with high potential for water quality impact must be inspected [*insert frequency, e.g. annually*].
 2. Facilities with medium potential for water quality impact must be inspected at least [*insert frequency, e.g. once every three years*].
 3. Facilities with low potential for water quality impact must be inspected at least [*insert frequency, e.g. once every 5 years*].

²⁹ 2008 MSGP Fact Sheet (www.epa.gov/npdcs/pubs/msgp2008_finalfs.pdf), with modifications

MS4 Permit Improvement Guide

4. Facilities with either a *[insert violation type]* written violation occurring in the previous year must be inspected at least *[insert frequency, e.g. annually]* until compliance is achieved.
 5. For facilities with no exposure of commercial or industrial activities to stormwater, no inspections are required. However, the permittee must continue to track these facilities for significant change in the exposure of their operations to stormwater.
- b. Scope of Inspection – Inspections must at a minimum:
1. Evaluate the facility's compliance with the Part 7.2 requirement to select, design, install, and implement stormwater control measures.
 2. Conduct a visual observation for evidence of unauthorized discharges, illicit connections, and potential discharge of pollutants to stormwater.
 3. Verify whether the facility is required to be authorized under the *[insert applicable NPDES general industrial stormwater permit]*, and whether the facility has in fact obtained such permit coverage.³⁰
 4. Evaluate the facility's compliance with any other relevant local stormwater requirements.
- c. Documentation Requirements – At a minimum, the permittee must document the following for each inspection:
- The inspection date and time;
- The name(s) and signature(s) of the inspector(s);
1. Weather information and a description of any discharges occurring at the time of the inspection;
 2. Any previously unidentified discharges of pollutants from the site;
 3. Any control measures needing maintenance or repairs;
 4. Any failed control measures that need replacement;
 5. Any incidents of noncompliance observed; and
 6. Any additional control measures needed to comply with the Permit Requirements.
- d. Track Inspections – Inspection findings must be tracked to ensure inspections are conducted at the frequency specified in Part 7.3.2.b., highlight and document the recidivism of noncompliant facilities, and aid follow up and enforcement activities.

7.3.3 Enforcement – The permittee must ensure that all necessary follow up and enforcement activities are conducted as necessary to require necessary implementation and maintenance of the control measures described in Part 7.2. The permittee is required to utilize the approved ERP for all enforcement actions.

³⁰ San Francisco Bay Region Municipal Regional Stormwater NPDES Permit (www.swrcb.ca.gov/sanfranciscobay/board_decisions/adopted_orders/2009/R2-2009-0074.pdf), with modifications

MS4 Permit Improvement Guide

Example Permit Requirement Rationale for the Fact Sheet

The permittee must design an inspection program that facilitates more frequent inspections of the highest priority facilities. (See 40 CFR 122.26(d)(iv)(C)(1)). This will help maximize use of the permittee's existing inspection resources and ensure that the permittee inspectors are the most visible and the most familiar with the facilities with the highest potential for water quality impact.

The permittee must develop a process for prioritizing inspections and designating all facilities in the industrial and commercial inventory as either a high, medium or low priority. The designation could occur by individual facility or by facility type. The prioritization for individual facilities may be adjusted after the first, or any subsequent, inspection (for example, if a facility is a high priority facility and the inspection reveals it has little potential for stormwater pollution, then the facility could be reprioritized as a low priority facility).

It is important that inspections be conducted in a thorough and consistent manner in accordance with a formal protocol for conducting an inspection. This protocol should be the basis for inspector training as well. Inspections should include a thorough walk-through of the facility.

The documentation of inspections is very important, not only when tracking noncompliance, but also to facilitate effective enforcement action when needed. A timeline of noncompliance and subsequent enforcement action is critical when escalating measures to gain compliance. Typically, the use of inspection forms facilitates complete and consistent documentation among inspectors and over time.

Recommendations for the Permit Writer

The permit writer may choose to define what criteria the permittee will use to determine the priority of each facility on its inventory. For example, the Phase I Los Angeles County MS4 permit specifies which facilities are Tier 1 and Tier 2 and provides the required inspection frequency for each. The permit writer could also automatically designate certain sets of industries to a certain priority category (e.g., all facilities subject to the State's Industrial General Permit could be designated as high priority facilities in the permit). If the permit does not define what criteria are to be used when prioritizing facilities, the permittee should be required to develop this protocol and submit it to the permitting authority for review.

The permit writer should review available industrial and commercial inventories to determine if more specific inspection frequencies should be set. For example, an MS4 with only 10 facilities in the inventory could probably inspect those facilities annually. However, an MS4 with over 2,000 facilities in the inventory may need to set the inspection frequency at a less frequent interval.

7.4 Staff Training

Example Permit Provision

7.4.1 The permittee must ensure that all staff whose primary job duties are implementing the industrial stormwater program is trained to conduct facility inspections. The training must cover what is required under this permit in terms of stormwater control measures, the requirements of other applicable Industrial Stormwater general permits or other related local requirements, the permittee's site inspection and documentation protocols, and enforcement procedures. Follow-up training must be provided every other year to address changes in procedures, techniques, or staffing. Permittees must document and maintain records of the training provided and the staff trained.³¹

Example Permit Requirement Rationale for the Fact Sheet

Inspectors responsible for conducting inspections at industrial/commercial facilities must be trained on the applicable stormwater requirements for the different types of facilities (i.e., industrial, commercial, other). Training must include a summary of federal, state, and local stormwater regulations that may apply to industrial/commercial facilities. Inspectors must be familiar with various types of stormwater control measures commonly used at the types of facilities typically found in the MS4 area and must be able to educate facility operators about such stormwater control measures. In addition, inspectors must understand and use the permittee's established enforcement response plan (see Chapter 1 of this Guide) to gain compliance as necessary. The inspection staff must be proficient in the enforcement escalation procedure and must properly document all enforcement actions accordingly per the ERP.

³¹ Western Washington Phase I MS4 Permit (www.ecy.wa.gov/programs/wq/stormwater/municipal/phaseIpermit/MODIFIEDpermitDOCS/PhaseIpermitSIGNED.pdf), with modifications

CHAPTER 8: MONITORING, EVALUATION, AND REPORTING

Introduction

Phase I MS4s are required to conduct discharge characterization, field screening and develop a monitoring program. Phase I MS4s are also required to conduct an assessment of controls. See 40 CFR 122.26(d)(1)(iii), (d)(2)(iii), and (d)(2)(v).

Phase II MS4 regulations allow, but do not specifically require, monitoring. Phase II MS4s are required to evaluate program compliance, the appropriateness of identified control measures, and progress toward achieving identified measurable goals. See 40 CFR 122.34(g).

There are many components involved in monitoring and evaluating the effectiveness of a municipal stormwater program. Any comprehensive monitoring program should have clear monitoring objectives to help determine compliance and water quality impacts.

Each monitoring program is unique and should be customized to the specific waterbodies, impairments, and pollutant sources of the MS4.

Evaluating the overall effectiveness of the municipal stormwater program should be done using information from the monitoring program, progress toward meeting measurable goals, and other indicators. Without assessing the effectiveness of the stormwater management program the permittee will not know which parts of the program need to be modified to protect and/or improve water quality and instead will essentially be operating blindly. Establishing a comprehensive monitoring and assessment program will enable the permittee to track progress in complying with permit provisions and implementing a program to protect water quality.

Included Concepts

- ▶ Consolidated information tracking system
- ▶ Development of a comprehensive monitoring and assessment program
- ▶ Evaluation of overall program effectiveness
- ▶ Requirements for annual reporting of MS4 activities

8.1 Consolidated Information Tracking System

Example Permit Provision

- 8.1.1 Within the first *[insert time frame which corresponds to the development of the monitoring program e.g. first two years of permit]*, the permittee must develop a tracking system to track the information required in the permit as well as the information required to be reported in the annual report (see Part 8.4).

Example Permit Requirement Rationale for the Fact Sheet

An important part of any municipal stormwater program is to document and track information on activities the permittee undertakes to comply with the Permit Requirements. Tracking should be integrated into each of the minimum measures. For example, tracking the location of illicit discharges may indicate that a specific area has a high incidence of motor oil being dumped into storm drains. Investigations may reveal that homeowners are changing the motor oil in their cars, but not properly disposing it. Therefore, the permittee will need to educate the homeowners in that area regarding proper disposal.

The permittee must develop a tracking system to monitor implementation of its various programs in order to document the permittee's compliance with its Permit Requirements, such as the number of construction sites and industrial facilities inspected. In addition, the tracking system will allow the permittee to monitor the compliance status of those entities within its jurisdiction, such as construction sites and industrial facilities, and to ensure compliance of municipally-owned and operated facilities.

Any tracking system should be coordinated with the monitoring and evaluation programs developed by the permittee. Ideally, a monitoring and evaluation program will link the "actions" (e.g., the inspections, maintenance, education and other activities the permittee implements) with the "results" (e.g., water quality monitoring data, improvements in environmental indicators) of the monitoring program.

In addition, adequate tracking is necessary to generate and provide reports of program progress not only to the permitting authority, but to a permittee's internal management for planning and funding purposes. Ideally, a MS4 permittee will have at least one person in charge of overall coordination, including tracking. While many departments or agencies might implement various stormwater program components, it is helpful for a single person or department to gather and analyze applicable data. This can be accomplished in a number of ways and will vary based on existing data tracking mechanisms used by a permittee, the data being captured and the reporting requirements the permittee must comply with. Ideally, the program would have a database accessible by all parties which specifies the required data. Lacking this, the permittee will need to coordinate all responsible parties. The permittee will need to ensure that responsible parties "mine" all data necessary to adequately represent the program and permit compliance, and specify adequate internal reporting deadlines to guarantee that the data is available in a timely manner for program planning, effectiveness assessments and permit reporting. Some permittees create reporting forms for program component managers to complete and submit by internal deadlines. Regardless of how the permittee coordinates the effort internally, without adequate tracking of data the permittees will not be able to submit annual reports to the permitting authority that provide the necessary information to determine permit compliance.

Recommendations for the Permit Writer

To assist the permittee in ensuring appropriate data is gathered and analyzed, the permitting authority should be very clear regarding annual reporting requirements. In addition, the text for this section should be tailored depending on the permittee. For example, some permittees may be able to develop a GIS-based system complete with the option to upload pictures and inspection reports versus a spreadsheet. In the text provided either system would meet the requirements, but more detailed information can be obtained with the GIS-based system.

8.2 Development of a Comprehensive Monitoring & Assessment Program

Example Permit Provision

8.2.1 The permittee must continue to implement, and revise as necessary, a comprehensive monitoring and assessment program. A description of this program must be included in the SWMP document. The monitoring and assessment program must be designed to meet the following objectives:

- a. Assess compliance with this permit;
- b. Measure the effectiveness of the permittee's stormwater management program;
- c. Assess the chemical, physical, and biological impacts to receiving waters resulting from stormwater discharges;
- d. Characterize stormwater discharges;
- e. Identify sources of specific pollutants;
- f. Detect and eliminate illicit discharges and illegal connections to the MS4; and
- g. Assess the overall health and evaluate long-term trends in receiving water quality.

NOTE: Because monitoring programs and requirements are very specific to the MS4 and local water quality impairments, permit writers are directed to the "Recommendations to the Permit Writer" section below for examples of comprehensive monitoring program Permit Requirements.

Example Permit Requirement Rationale for the Fact Sheet

Without clear monitoring objectives and a detailed monitoring plan, it will be difficult for permittees and permitting authorities to evaluate the effectiveness of the municipal stormwater program.

There are numerous factors that should be examined while setting up the water quality monitoring portion of the comprehensive program. Understanding and considering climatic conditions such as precipitation patterns, temperature, and seasonal variations will ensure the study design will collect data that are representative of typical storms in the area and that sampling occurs during times of the year when it is most logical to do so. Acknowledging the different types of land uses within the area will also help the permittee to prioritize monitoring efforts based on the areas most likely to be impacted by stormwater. The type of waterbody monitored must also be considered when selecting sampling locations since pollutants behave differently depending on the environment thereby impacting sampling protocols. For example, sampling in a freshwater lake involves different protocols than monitoring in a tidally influenced river or a first order stream. Waterbody type can also influence the data results and conclusions (e.g. freshwater wetlands typically have high denitrification rates that will likely impact the results of nitrate sampling).

MS4 Permit Improvement Guide

Selection of specific sampling locations is also very important. If particular sites are of concern, then monitoring both above and below the sites to figure out their contributions to the overall water quality issues may make sense. Also, the actual location in the waterbody is important to specify for consistency. For example, should samples be taken close to the stream bank or in the center of the waterbody, in riffles or pools? The answers to these questions, of course, depend on the goals of the monitoring and the constituents (biological, chemical, hydrological) being examined.

In addition, the number and frequency of samples collected and stream assessments performed will determine how robust the data will be (see page 287 in *National Research Council's Report Urban Stormwater Management in the United States (2009)* available at www.epa.gov/npdes/pubs/nrc_stormwaterreport.pdf). Monitoring may or may not be tied to specific wet weather events (i.e. within 72 hours after a rainfall event). A combination of specific wet weather samples and dry weather samples may be appropriate.

Establishing objectives with associated indicators (environmental or administrative) for each minimum measure can help put each component into perspective when considering the overall program. Indicators are one way to evaluate the success of the program from the overall program level. Developing standard environmental indicators is a critical step to evaluate the SWMP. Permittees need practical tools, such as these indicators, in order to determine if their stormwater programs are working, and that help elucidate where additional efforts may be most critical. Environmental indicators should be selected based on the type (estuarine/freshwater/brackish) and condition (impaired/non-impaired) of the waterbody to which stormwater is discharged as well as the intended use of the area where the stormwater is discharged (source water protection area, etc.).

In addition, permittees should document certain administrative efforts associated with developing and implementing their SWMPs. In this context 'administrative' is considered quite broad, including such things as control measures, inspection programs, policies and rules, MS4 system scope and condition, educational efforts and any other variable or outcome that could reflect on the quality of a stormwater program other than the actual environmental quality outcomes, which are covered under 'Environmental Indicators'.

Good administrative indicators are numerous, and good suites of indicators will vary from one community to another. More information can be obtained on each of the environmental and administrative indicators listed by going to the Stormwater Manager's Resource Center (www.stormwatercenter.net) and selecting "Monitor/Assess" on the left navigation bar.

Several protocols have been developed to assess the effectiveness of stormwater control measures:

- Guidance for Evaluating Emerging Stormwater Treatment Technologies, Technology Assessment Protocol - Ecology (TAPE) www.ecy.wa.gov/biblio/0210037.html. This guidance document's primary purpose is to establish a testing protocol and process for evaluating and reporting on the performance and appropriate uses of emerging stormwater treatment technologies.
- Technology Acceptance Reciprocity Partnership (TARP) Protocol for Stormwater Best Management Practice Demonstrations www.dep.state.pa.us/dep/deputate/pollprev/techservices/tarp/pdf/Tier2protocol.pdf. The purpose of the TARP

MS4 Permit Improvement Guide

Protocol is to provide a uniform method for demonstrating stormwater technologies and developing test quality assurance (QA) plans for certification or verification of performance claims.

- **BMP Performance Verification Checklist.** This is a tool that helps permittees provide a consistent set of questions for applicants proposing to use manufactured and proprietary BMP. It is available as Tool # 8 of the Center for Watershed Protection's *Managing Stormwater in Your Community*. The checklist is accompanied by an explanation and instructions for using the checklist, technical appendices, and a matrix that compares existing verification protocols, such as TARP and TAPE.

Additional monitoring resources include:

- CWP, 2008, *Monitoring to Demonstrate Environmental Results: Guidance to Develop Local Stormwater Monitoring Studies Using Six Example Study Designs* (www.cwp.org)
- Geosyntec Consultants and Wright Water Engineers, 2009, *Urban Stormwater BMP Performance Monitoring*, (bmpdatabase.org/MonitoringEval.htm)
- CASQA, 2007, *Municipal Stormwater Program Effectiveness Assessment Guidance* (www.casqa.org)

Recommendations for the Permit Writer

Because of the site-specific nature and variability of these monitoring programs between permittees, the detailed requirements should be provided by each permit writer. For example, the Phase I regulations included specific monitoring requirements while the Phase II regulations allow, but do not specifically require monitoring. To assist permit writers, several examples of monitoring requirements from existing MS4 permits are listed below:

- Baltimore County, MD Phase I MS4 permit (issued 2005); see the watershed assessment and planning requirements (Part II.F) and assessment of controls (Part II.H)
www.mde.state.md.us/assets/document/sedimentStormwater/MSSPermit/BA%20final%20permit.pdf
- Southern California Regional Bioassessment Monitoring Program (this is a regional monitoring program involving coastal counties in Southern California)
www.socalsmc.org/Docs/SMC-DesignofBioassessmentRegionalMonitoringProgram.pdf
- San Diego, CA Phase I MS4 Permit (issued 2007); see Receiving Waters and Urban Runoff Monitoring and Reporting Program.
www.waterboards.ca.gov/sandiego/water_issues/programs/stormwater/docs/sd_permit_r9_2007_0001/2007_0001final.pdf

The permit writer could consider the role of partnerships among the MS4s in establishing and implementing the monitoring programs so that any data collected is robust, useful, and meaningful. In addition, communities may benefit more by working with local organizations and/or neighboring communities who are already collecting similar data. By doing so resources may be used more efficiently and results of testing may be more robust.

MS4 Permit Improvement Guide

The permit writer should also require the permittee to assess the effectiveness of the SWMP in meeting applicable Permit Requirements. The sampling protocols developed must support the goals of the monitoring program. The monitoring and assessment program must include water quality monitoring as well as an assessment of environmental and administrative indicators. Along these lines, the permit writer could also add requirements such as the ones provided below:

Water Quality Monitoring

a. The Permittee must develop a water quality monitoring program that includes [insert specific monitoring programs and requirements, such as:

- Ambient receiving water monitoring,
- Biological monitoring,
- Control measure performance monitoring, or
- Discharge (wet weather) monitoring

Because the detailed monitoring program requirements are very unique to each MS4, the permitting authority should insert here the specific details of the relevant monitoring program, such as monitoring type, frequency, location, etc.]

- b. When determining water quality monitoring components, the permittee must examine and consider a variety of factors, including, but not limited to:
- Climatic conditions, including precipitation patterns, temperature, and seasonal variations
 - Land uses in the MS4
 - Waterbody type
- c. The permittee must consider and address specific sampling quality assurance/quality control protocols, including, but not limited to:
- Specific chemical constituents (pollutants), biological stream indicators, and physical stream indicators that will be monitored to best achieve the purpose of the monitoring
 - Sampling locations
 - Number and frequency of sample collection and assessments
 - Timing of sample collection
- d. The permittee must determine if any similar monitoring is occurring within the MS4 and if it is logical to link efforts.

Environmental Indicators

As part of the comprehensive monitoring and assessment program, the permittee must identify and track at least [insert number of indicators to be tracked] environmental

MS4 Permit Improvement Guide

indicators from each category listed below (physical and hydrologic indicators; biological indicators; water quality indicators). The indicators must be appropriate to assess if the SWMP is meeting goals and objectives:

Physical and hydrological indicators	Biological indicators	Water quality indicators
<ul style="list-style-type: none"> • Stream widening/downcutting • Physical habitat quality • Impacted dry weather flows • Increased flooding frequency • Stream temperature monitoring 	<ul style="list-style-type: none"> • Fish assemblage analysis • Macro-invertebrate assemblage • Single species indicator • Composite indicators • Other biological indicators 	<ul style="list-style-type: none"> • Water quality-pollutant constituent monitoring • Toxicity testing • Non-point source loadings • Exceedance frequencies of water quality standards • Sediment contamination • Human health criteria

Administrative indicators

As part of the comprehensive monitoring and assessment program, the permittee must identify and track at least [insert number of indicators to be tracked] administrative indicator from each category listed below (social indicators; programmatic indicators; site indicators). The indicators must be appropriate to assess if the SWMP is meeting goals and objectives:

Social indicators	Programmatic indicators	Site indicators
<ul style="list-style-type: none"> • Public attitude surveys • Industrial/commercial pollution prevention • Public involvement and monitoring • User perception 	<ul style="list-style-type: none"> • Number of illicit connections identified and corrected • Number of control measures installed, inspected, and maintained • Permitting and compliance • Growth and development 	<ul style="list-style-type: none"> • Control measure performance monitoring • Industrial site compliance monitoring

Performance Monitoring of Stormwater Controls

When monitoring the performance of stormwater controls, EPA recommends that percent removal efficiencies are not calculated and compared since results can be misleading because the percentages may be based on differing levels of the influent concentration (see cfpub.epa.gov/npdes/stormwater/urbanbmp/bmptopic.cfm#percentremoval for further discussion; also see *National Research Council's Report Urban Stormwater Management in the United States (2009)* available at www.epa.gov/npdes/pubs/nrc_stormwaterreport.pdf).

Modeling can also be a useful tool to quantify the impacts of municipal stormwater management. The following resources provide summaries and reviews of different types of models available to

MS4 Permit Improvement Guide

determine existing loading from an MS4 as well as the effects expected from various stormwater controls.

1. USEPA Handbook for Developing Watershed Plans to Restore and Protect Our Waters
www.epa.gov/nps/watershed_handbook/

Chapter 8 of this document focuses on methods for estimating pollutant loads, including the use of watershed models. This chapter provides assistance in selecting and applying watershed models to estimate pollutant loads from existing conditions.

2. USEPA TMDL Model Evaluation and Research Needs
www.epa.gov/nrmrl/pubs/600r05149/600r05149.htm

This report documents the review of more than 60 available watershed and receiving water models. It discusses model selection on the basis of model capabilities and provides a series of tables rating the capabilities or applicability the models using the categories of TMDL endpoints, general land and water features, special land processes, special water processes, and application considerations including the selection of appropriate best management practices and their water quality impacts. The document also provides individual fact sheets for each reviewed model.

8.3 Evaluation of Overall Program Effectiveness

Example Permit Provision

8.3.1 *Annual Effectiveness Assessment* – The annual effectiveness assessment must:

- a. Use the monitoring and assessment data described in Part 8.2 to specifically assess the effectiveness of each of the following:
 1. Each significant activity/control measures or type of activity/control measure implemented;
 2. Implementation of each major component of the Stormwater Management Program (Public Education/Involvement, Illicit Discharges, Construction, Post-Construction, Good Housekeeping); and
 3. Implementation of the Stormwater Management Program as a whole.
- b. Identify and use measurable goals, assessment indicators, and assessment methods for each of the items listed in Part 8.3.1.a above.
- c. Document the permittee's compliance with permit conditions.

8.3.2 Based on the results of the effectiveness assessment, the permittee must annually review its activities or control measures to identify modifications and improvements needed to maximize SWMP effectiveness, as necessary to achieve compliance with this permit. The permittee must develop and implement a plan and schedule to address the identified modifications and improvements. Municipal activities/control

MS4 Permit Improvement Guide

measures that are ineffective or less effective than other comparable municipal activities/control measures must be replaced or improved upon by implementation of more effective municipal activities/control measures.

8.3.3 As part of its Annual Reports, the permittee must report on its SWMP effectiveness assessment as implemented under Part 8.3.1 above.

Example Permit Requirement Rationale for the Fact Sheet

A key requirement in the stormwater Phase II rule is a report (40 CFR 122.34(g)(3)) that includes "the status of compliance with permit conditions, an assessment of the appropriateness of identified [control measures] and progress towards achieving identified measurable goals for each of the minimum control measures." This assessment is critical to the stormwater program framework which uses the iterative approach of implementing controls, conducting assessments, and designating refocused controls leading toward attainment of water quality standards.

Building on the monitoring and assessment program developed in Part 8.2, the permittee must conduct an annual effectiveness assessment to assess the effectiveness of significant control measures, SWMP components, and the SWMP as a whole. The California Stormwater Quality Association's (CASQA) *Municipal Stormwater Program Effectiveness Guidance* describes strategies and methods for assessing effectiveness, including examples of effectiveness assessment for each SWMP program component. The CASQA Effectiveness Guidance is available at www.casqa.org for purchase. A two-hour EPA webcast focusing on the CASQA Guide is also available (available at www.epa.gov/npdes/training under "Assessing the Effectiveness of Your Municipal Stormwater Program"). A resources document from the webcast includes a 10 page summary of the Guide and example pages from the municipal chapter (www.epa.gov/npdes/outreach_files/webcast/jun0408/110961/municipal_resources.pdf).

The *Municipal Stormwater Program Effectiveness Assessment Guidance* synthesizes information on designing and conducting program effectiveness assessments. The document also explains how to select certain methods based on programmatic outcomes and goals. The reader is led through a series of questions and case studies to demonstrate how proper assessments are selected. Techniques are related to different level of outcomes: level one – documenting activities, level two – raising awareness, level 3 – changing behavior, level 4 – reducing loads from sources, level 5 – improving runoff quality, and level 6 – protecting receiving water quality. The Guide includes fact sheets for all six NPDES program elements, outlining methods and techniques for assessing effectiveness of each program.

Recommendations for the Permit Writer

Adaptive management is the appropriate process for assessing new opportunities for improving program effectiveness in controlling stormwater pollution. The permit writer should require the permittee to use adaptive management throughout the permit term to assess options for improving controls on stormwater discharges as compared with measurable goals and demonstrated by monitoring and assessment protocols. The permit writer should have the permittee monitor and

MS4 Permit Improvement Guide

assess the data and analyses required under the permit as well as applicable information from other sources in the adaptive management process.

In addition, the permit writer should have the permittee assess and modify, as necessary, any or all existing SWMP components and adopt new or revised SWMP components to optimize reductions in stormwater pollutants through an iterative process. This iterative process should include routine assessment of the need to further improve water quality and protect beneficial uses, review of available technologies and practices to accomplish the needed improvement, and evaluate resources available to implement the technologies and practices.

8.4 Requirements for Annual Reporting of MS4 Activities

Example Permit Provision

8.4.1 Summary Annual Report - The Permittee must submit annual reports on or before *[specify deadline, e.g., the anniversary date of this permit]* for the reporting period *[specify the reporting period, e.g., July 1-June 30]*. The Permittee must use the Summary MS4 Annual Report template in Appendix A to document a summary of the past year activities. All of the information required on this form must be completed.

8.4.2 Detailed Annual Report - The Permittee must also submit a detailed annual report that addresses, for the activities described in the SWMP document required in Part 1.1, the following:

- A summary of past year activities, including where available, specific quantities achieved and summaries of enforcement actions. See Part 8.4.3 for required information specific to certain SWMP areas.
- A description of the effectiveness of each SWMP program component or activity (see Part 8.3); and
- Planned activities and changes for the next reporting period, for each SWMP program component or activity.
- Detailed fiscal analysis described in Part 1.4.2.

8.4.3 *[Specify any additional information and/or data pertaining to implementation of priority activities the Permitting Authority would like to see in Annual Reports, e.g. a list of green roofs (with square footage) installed in the MS4, a summary of water quality monitoring data collected for a specific waterbody, etc.]*

The Annual Report must clearly refer to the Permit Requirements, and describe in quantifiable terms, the status of activities undertaken to comply with each requirement.

Example Permit Requirement Rationale for the Fact Sheet

In general, an annual report must document and summarize implementation of the SWMP during the previous year and evaluate program results and describe planned changes towards continuous improvement. The annual report also can serve as a "state of the SWMP" report for the general public or other stakeholders in the community. While records are to be kept and made available to the public, the annual report is an excellent summary document to provide as well.

Recommendations for the Permit Writer

EPA recommends using its Summary Annual Report Template (see Appendix A) in this guidance in order to obtain summary information about the status of MS4 programs. In addition to the summary annual report template, permittees must also submit a more detailed annual report.

The permit writer may determine that additional, more detailed, information is needed to determine compliance with the Permit Requirements. Even if these reporting details are not required within the permit, the permitting authority and enforcement officials can still request them at any time or during a program audit.

MS4 permits should require permittees to summarize and analyze data concerning the effectiveness of the SWMP and submit the analysis to the permitting authority. For example, the permittees should address such questions as:

- For illicit discharge data, what are the most prevalent sources and pollutants in the illicit discharge data, and where are these illicit discharges occurring? How many illicit discharges have been identified, and how many of those have been resolved? How many outfalls or screening points were visually screened, how many had dry weather discharges or flows, at how many were field analyses completed and for what parameters, and at how many were samples collected and analyzed? Does the MS4 need to conduct more inspections in these areas, or develop more specific outreach targeting these sources and pollutants?
- For the construction data, what are the most common construction violations, and are there any trends in the data (e.g., construction operators who receive more violations than others, areas of the MS4 with more violations, need to refine guidance or standards to more clearly address common violations). How has the permittee responded to these trends? Over the last year, how many construction site plan reviews were completed and approved? How many inspections were conducted, how many noncompliant sites were identified, and how many enforcement actions (and of what type) were taken?

At a minimum, the permit should require that the annual report clearly illustrate three key items for each SWMP area:

- **Summary of the Year's Activities.** The summary should describe and quantify program activities for each SWMP component. Responsible persons, agencies, departments or co-permittees should be included. Each activity should be described in relation to achievement of established goals or performance standards.

MS4 Permit Improvement Guide

- **Description of SWMP Effectiveness.** An annual report should not only describe the previous year's activities, but should also highlight the SMWP's effectiveness (see Part 8.3) using the indicators required in Part 8.2.
- **Planned Activities and Changes.** The annual report should describe activities planned for the next year highlighting any changes made to improve control measures or program effectiveness.

Also, although the stormwater Phase II rule requires reports, after the first permit term, to be submitted in only years two and four of the permit term, EPA strongly encourages annual reports for all permittees.

APPENDIX A: SUMMARY ANNUAL REPORT TEMPLATE

**National Pollutant Discharge Elimination System Stormwater Program
 Small MS4 Report Form**

The purpose of this report is to contribute information to an evaluation of the NPDES small municipal separate storm sewer system (MS4) permit program. Consistent with 40 CFR §122.37 the U.S. Environmental Protection Agency is assessing the status of the program nation-wide. A "no" answer to a question does not necessarily mean noncompliance with your permit or with the federal regulations. In order to establish the range of variability in the program it is necessary to ask questions along a fairly broad performance continuum. Your permitting authority may use some of this information as one component of a compliance evaluation.

1. MS4 Information

Name of MS4 _____

Name of Contact Person (First) _____ (Last) _____ (Title) _____

Telephone (including area code) _____ Email _____

Mailing Address _____

City _____ State _____ ZIP code _____

What size population does your MS4 serve? _____ NPDES number _____

What is the reporting period for this report? (mm/dd/yyyy) From _____ to _____

2. Water Quality Priorities

A. Does your MS4 discharge to waters listed as impaired on a state 303(d) list? Yes No

B. If yes, identify each impaired water, the impairment, whether a TMDL has been approved by EPA for each, and whether the TMDL assigns a wasteload allocation to your MS4. Use a new line for each impairment, and attach additional pages as necessary.

Impaired Water	Impairment	Approved TMDL		TMDL assigns WLA to MS4	
		<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No
_____	_____	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Yes	<input type="checkbox"/> No

C. What specific sources contributing to the impairment(s) are you targeting in your stormwater program?

D. Do you discharge to any high-quality waters (e.g., Tier 2, Tier 3, outstanding natural resource waters, or other state or federal designation)? Yes No

E. Are you implementing additional specific provisions to ensure their continued integrity? Yes No

Small MS4 Annual Report Form (cont)

3. Public Education and Public Participation

- A. Is your public education program targeting specific pollutants and sources of those pollutants? Yes No
- B. If yes, what are the specific sources and/or pollutants addressed by your public education program?

- C. Note specific successful outcome(s) (e.g., quantified reduction in fertilizer use; NOT tasks, events, publications) fully or partially attributable to your public education program during this reporting period.

- D. Do you have an advisory committee or other body comprised of the public and other stakeholders that provides regular input on your stormwater program? Yes No

4. Construction

- A. Do you have an ordinance or other regulatory mechanism stipulating:
- | | | |
|--|------------------------------|-----------------------------|
| Erosion and sediment control requirements? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
| Other construction waste control requirements? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
| Requirement to submit construction plans for review? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
| MS4 enforcement authority? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
- B. Do you have written procedures for:
- | | | |
|-------------------------------|------------------------------|-----------------------------|
| Reviewing construction plans? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
| Performing inspections? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
| Responding to violations? | <input type="checkbox"/> Yes | <input type="checkbox"/> No |
- C. Identify the number of active construction sites ≥ 1 acre in operation in your jurisdiction at any time during the reporting period. _____
- D. How many of the sites identified in 4.C did you inspect during this reporting period? _____
- E. Describe, on average, the frequency with which your program conducts construction site inspections.

- F. Do you prioritize certain construction sites for more frequent inspections? Yes No
If Yes, based on what criteria? _____
- G. Identify which of the following types of enforcement actions you used during the reporting period for construction activities, indicate the number of actions, or note those for which you do not have authority:
- | | | | |
|------------------------------|-----------------------|---------|---------------------------------------|
| <input type="checkbox"/> Yes | Notice of violation | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Administrative fines | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Stop Work Orders | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Civil penalties | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Criminal actions | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Administrative orders | # _____ | No Authority <input type="checkbox"/> |
| <input type="checkbox"/> Yes | Other _____ | # _____ | |
- H. Do you use an electronic tool (e.g., GIS, data base, spreadsheet) to track the locations, inspection results, and enforcement actions of active construction sites in your jurisdiction? Yes No
- I. What are the 3 most common types of violations documented during this reporting period?

- J. How often do municipal employees receive training on the construction program? _____

Small MS4 Annual Report Form (cont)

5. Illicit Discharge Elimination

- A. Have you completed a map of all outfalls and receiving waters of your storm sewer system? Yes No
- B. Have you completed a map of all storm drain pipes and other conveyances in the storm sewer system? Yes No
- C. Identify the number of outfalls in your storm sewer system. _____
- D. Do you have documented procedures, including frequency, for screening outfalls? Yes No
- E. Of the outfalls identified in 5.C, how many were screened for dry weather discharges during this reporting period?

- F. Of the outfalls identified in 5.C, how many have been screened for dry weather discharges at any time since you obtained MS4 permit coverage? _____
- G. What is your frequency for screening outfalls for illicit discharges? Describe any variation based on size/type.

- H. Do you have an ordinance or other regulatory mechanism that effectively prohibits illicit discharges? Yes No
- I. Do you have an ordinance or other regulatory mechanism that provides authority for you to take enforcement action and/or recover costs for addressing illicit discharges? Yes No
- J. During this reporting period, how many illicit discharges/illegal connections have you discovered? _____
- K. Of those illicit discharges/illegal connections that have been discovered or reported, how many have been eliminated?

- L. How often do municipal employees receive training on the illicit discharge program? _____

6. Stormwater Management for Municipal Operations

- A. Have stormwater pollution prevention plans (or an equivalent plan) been developed for:
 - All public parks, ball fields, other recreational facilities and other open spaces Yes No
 - All municipal construction activities, including those disturbing less than 1 acre Yes No
 - All municipal turf grass/landscape management activities Yes No
 - All municipal vehicle fueling, operation and maintenance activities Yes No
 - All municipal maintenance yards Yes No
 - All municipal waste handling and disposal areas Yes No
 - Other _____
- B. Are stormwater inspections conducted at these facilities? Yes No
- C. If Yes, at what frequency are inspections conducted? _____
- D. List activities for which operating procedures or management practices specific to stormwater management have been developed (e.g., road repairs, catch basin cleaning).

- E. Do you prioritize certain municipal activities and/or facilities for more frequent inspection? Yes No
- F. If Yes, which activities and/or facilities receive most frequent inspections? _____
- G. Do all municipal employees and contractors overseeing planning and implementation of stormwater-related activities receive comprehensive training on stormwater management? Yes No
- H. If yes, do you also provide regular updates and refreshers? Yes No
- I. If so, how frequently and/or under what circumstances? _____

Small MS4 Annual Report Form (cont)

7. Long-term (Post-Construction) Stormwater Measures

- A. Do you have an ordinance or other regulatory mechanism to require:
- Site plan reviews for stormwater/water quality of all new and re-development projects? Yes No
 - Long-term operation and maintenance of stormwater management controls? Yes No
 - Retrofitting to incorporate long-term stormwater management controls? Yes No
- B. If you have retrofit requirements, what are the circumstances/criteria?

C. What are your criteria for determining which new/re-development stormwater plans you will review (e.g., all projects, projects disturbing greater than one acre, etc.) _____

D. Do you require water quality or quantity design standards or performance standards, either directly or by reference to a state or other standard, be met for new development and re-development? Yes No

E. Do these performance or design standards require that pre-development hydrology be met for:

- Flow volumes Yes No
- Peak discharge rates Yes No
- Discharge frequency Yes No
- Flow duration Yes No

F. Please provide the URL/reference where all post-construction stormwater management standards can be found.

G. How many development and redevelopment project plans were reviewed during the reporting period to assess impacts to water quality and receiving stream protection? _____

H. How many of the plans identified in 7.G were approved? _____

I. How many privately owned permanent stormwater management practices/facilities were inspected during the reporting period? _____

J. How many of the practices/facilities identified in I were found to have inadequate maintenance? _____

K. How long do you give operators to remedy any operation and maintenance deficiencies identified during inspections?

L. Do you have authority to take enforcement action for failure to properly operate and maintain stormwater practices/facilities? Yes No

M. How many formal enforcement actions (i.e., more than a verbal or written warning) were taken for failure to adequately operate and/or maintain stormwater management practices? _____

N. Do you use an electronic tool (e.g., GIS, database, spreadsheet) to track post-construction BMPs, inspections and maintenance? Yes No

O. Do all municipal departments and/or staff (as relevant) have access to this tracking system? Yes No

P. How often do municipal employees receive training on the post-construction program? _____

8. Program Resources

A. What was the annual expenditure to implement MS4 permit requirements this reporting period? _____

B. What is next year's budget for implementing the requirements of your MS4 NPDES permit? _____

Small MS4 Annual Report Form (cont)

C. This year what is/are your source(s) of funding for the stormwater program, and annual revenue (amount or percentage) derived from each?

Source: _____ Amount \$ _____ OR % _____
 Source: _____ Amount \$ _____ OR % _____
 Source: _____ Amount \$ _____ OR % _____

D. How many FTEs does your municipality devote to the stormwater program (specifically for implementing the stormwater program; not municipal employees with other primary responsibilities)? _____

E. Do you share program implementation responsibilities with any other entities? Yes No

Entity	Activity/Task/Responsibility	Your Oversight/Accountability Mechanism
_____	_____	_____
_____	_____	_____
_____	_____	_____

9. Evaluating/Measuring Progress

A. What indicators do you use to evaluate the overall effectiveness of your stormwater management program, how long have you been tracking them, and at what frequency? These are not measurable goals for individual management practices or tasks, but large-scale or long-term metrics for the overall program, such as macroinvertebrate community indices, measures of effective impervious cover in the watershed, indicators of in-stream hydrologic stability, etc.

Indicator	Began Tracking (year)	Frequency	Number of Locations
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____
_____	_____	_____	_____

B. What environmental quality trends have you documented over the duration of your stormwater program? Reports or summaries can be attached electronically, or provide the URL to where they may be found on the Web.

Small MS4 Annual Report Form (cont)

10. Additional Information

In the space below, please include any additional information on the performance of your MS4 program. If providing clarification to any of the questions on this form, please provide the question number (e.g., 2C) in your response.

Certification Statement and Signature

I certify that all information provided in this report is, to the best of my knowledge and belief, true, accurate and complete. Yes

Federal regulations require this application to be signed as follows: **For a municipal, State, Federal, or other public facility:** by either a principal executive or ranking elected official.

Name of Certifying Official, Title

Date (mm/dd/yyyy)

Submit

APPENDIX B: DEFINITIONS

Commencement of Construction – the initial disturbance of soils associated with clearing, grading, or excavating activities or other construction-related activities (e.g., stockpiling of fill material). (Source: 2008 CGP)

Control Measure – any best management practice (BMP) or other method used to prevent or reduce the discharge of pollutants to waters of the United States. (Source: 2008 CGP)

Discharge – when used without qualification means the “discharge of a pollutant.” (Source: 2008 CGP)

Discharge of Stormwater Associated with Construction Activity – as used in this permit, refers to a discharge of pollutants in stormwater from areas where soil disturbing activities (e.g., clearing, grading, or excavation), construction materials or equipment storage or maintenance (e.g., fill piles, borrow area, concrete truck chute washdown, fueling), or other industrial stormwater directly related to the construction process (e.g., concrete or asphalt batch plants) are located. (Source: 2008 CGP)

Illicit Discharge - any discharge to a municipal separate storm sewer that is not composed entirely of storm water except discharges pursuant to a NPDES permit (other than the NPDES permit for discharges from the municipal separate storm sewer) and discharges resulting from fire fighting activities. (Source: 40 CFR 122.26)

Large Construction Activity – is defined at 40 CFR §122.26(b)(14)(x) and incorporated here by reference. A large construction activity includes clearing, grading, and excavating resulting in a land disturbance that will disturb equal to or greater than five acres of land or will disturb less than five acres of total land area but is part of a larger common plan of development or sale that will ultimately disturb equal to or greater than five acres. Large construction activity does not include routine maintenance that is performed to maintain the original line and grade, hydraulic capacity, or original purpose of the site. (Source: 2008 CGP)

Non-Structural Controls – preventative actions that involve management and source controls. Refer also to 40 CFR 122.34(b)(5)(c)(iii). (Source: 40 CFR 122.26)

Qualified Personnel – A person knowledgeable in the principles and practice of erosion and sediment controls who possesses the skills to assess conditions at the construction site that could impact stormwater quality and to assess the effectiveness of any sediment and erosion control measures selected to control the quality of stormwater discharges from the construction activity. (Source: EPA's 2008 Construction General Permit)

Receiving Water – the “Water of the United States” as defined in 40 CFR §122.2 into which the regulated stormwater discharges. (Source: 2008 CGP)

Small Construction Activity – includes clearing, grading, and excavating resulting in a land disturbance that will disturb equal to or greater than one (1) acre and less than five (5) acres of land or will disturb

less than one (1) acre of total land area but is part of a larger common plan of development or sale that will ultimately disturb equal to or greater than one (1) acre and less than five (5) acres. Small construction activity does not include routine maintenance that is performed to maintain the original line and grade, hydraulic capacity, or original purpose of the site. (Source: 2008 CGP)

Stormwater control measure – see control measure.

Structural Control - physically designed, installed, and maintained practices used to prevent or reduce the discharge of pollutants in stormwater, to minimize erosion, and/or to minimize the impacts of stormwater on waterbodies.

Wasteload Allocation – the portion of a receiving water's loading capacity that is allocated to one of its existing or future point sources of pollution. Wasteload allocations constitute a type of water quality-based effluent limitation. (40 CFR 130.2)

ATTACHMENT 44

Program Evaluation Report

Riverside Area Stormwater Program: Cities of Corona, Moreno Valley and Riverside (NPDES Permit No. CAS 618033)

Executive Summary

Tetra Tech, Inc., with assistance from the California Regional Water Quality Control Board, Santa Ana Region (Regional Board), conducted a program evaluation of 3 of the 14 co-permittees implementing the Riverside Area Stormwater Program in May 2004. The purpose of the program evaluation was to determine the co-permittees' compliance with the National Pollutant Discharge Elimination System (NPDES) permit (CAS 618033 and Board Order R8-2002-0011) and to evaluate the current implementation status of the co-permittees' Urban Runoff Program (Program). The program evaluation included an in-field verification of program implementation. The three co-permittees evaluated were the cities of Corona, Moreno Valley, and Riverside.

This program evaluation report identifies potential permit violations, program deficiencies, and positive attributes. This report is not a formal finding of violation. Potential permit violations are areas of concern that the Regional Board staff should review to determine whether a violation has occurred. Program deficiencies are areas of concern for successful program implementation. Positive attributes indicate overall progress in implementing the Program.

The following potential permit violations are considered the most significant:

- The cities are not taking adequate steps to comprehensively evaluate program effectiveness.
- It is unclear whether the co-permittees are fully implementing the requirements in the New Development Guidelines (Supplement A to the DAMP).
- The co-permittees lack adequate guidance for reviewing new development project plans to assist with implementation of Supplement A and Water Quality Management Plans (WQMPs).
- The City of Corona does not adequately prioritize construction sites.
- The City of Corona lacks documentation on how it prioritizes industrial and commercial facilities.
- The City of Moreno Valley lacks criteria for designating priority levels for industrial and commercial facilities.

- The City of Moreno Valley needs to develop a septic system program to prevent system failures and to replace systems that have already failed.
- The City of Riverside's construction inspectors lack adequate inspection forms, inspection procedures, and training.
- The City of Riverside does not adequately identify and prioritize construction sites.
- The City of Riverside's corporation yard lacks adequate practices to prevent stormwater contamination.
- The City of Riverside's corporation yard lacks a site-specific Urban Runoff Pollution Prevention Plan.
- The City of Riverside does not have written standards, guidance, or training for the maintenance and inspection of structural stormwater controls.

The following program deficiency is considered significant for improvement of the program:

- The cities have not developed city-specific local stormwater management plans.

Several elements of the co-permittees' programs were particularly notable:

- The City of Corona requires a cash deposit for erosion control best management practices (BMPs).
- The City of Moreno Valley has implemented an annual maintenance charge for the City to maintain post-construction water quality BMPs.
- The City of Riverside has developed a GIS database that tracks routine inspections and other activities conducted by the Industrial Waste Division.

1.0 Introduction

1.1 Program Evaluation Purpose

The purpose of the program evaluation was to determine the co-permittees' compliance with their National Pollutant Discharge Elimination System (NPDES) permit (CAS 618033 and Board Order R8-2002-0011) and to evaluate the current implementation status of the co-permittees' Urban Runoff Program (Program) with respect to EPA's stormwater regulations. Secondary goals included the following:

- Review the overall effectiveness of the Program.
- Identify and document positive elements of the Program that could benefit other Phase I and Phase II municipalities.
- Acquire data to assist in reissuance of the permit.

40 CFR 122.41(i) provides the authority to conduct the program evaluation.

1.2 Permit History

The NPDES stormwater permit was issued on October 25, 2002, and is scheduled to expire on October 26, 2007. The current permit, the third issued to the co-permittees, requires each co-permittee to implement an Urban Runoff Program, including the best management practices (BMPs) identified in the area-wide Drainage Area Management Plan (DAMP).

1.3 Logistics and Program Evaluation Preparation

Before initiating the on-site program evaluation, Tetra Tech, Inc., reviewed the following Program materials:

- NPDES Permit No. CAS 618033
- Santa Ana Region DAMP
- Santa Ana Region Enforcement/Compliance Strategy (December 20, 2001)
- Santa Ana Region Municipal Facilities Strategy (June 1997)
- Appendix C, Supplement A (New Development Guidelines), of the DAMP
- Draft Water Quality Management Plan (WQMP) (April 30, 2004)
- 2002 annual report of each co-permittee
- Regional Board correspondence with each co-permittee
- Co-permittees' Web sites

On May 11–13, 2004, Tetra Tech, Inc., with assistance from the Regional Board, conducted the program evaluation. The evaluation schedule was as follows:

Tuesday, May 11	Wednesday, May 12	Thursday, May 13
<ul style="list-style-type: none"> • Program evaluation kickoff meeting • Program Management • Municipal Facilities and Activities (field and office) • Construction and New Development (office) 	<ul style="list-style-type: none"> • Construction (field) • Industrial and Commercial (office) • Illicit Discharge (office) 	<ul style="list-style-type: none"> • Industrial and Commercial (field) • Education and Outreach • Program Effectiveness • Reporting • Program evaluation outbrief meeting

Upon completion of the evaluation, an outbrief was held to discuss the preliminary findings. During the outbrief, the attendees were informed that the findings were to be considered preliminary pending further review by EPA and the Regional Board.

1.4 Program Areas Evaluated

The following program areas were evaluated:

- Program Management, including the co-permittees' assessment of program effectiveness
- Municipal Facilities and Activities
- Industrial and Commercial Inspections
- Construction
- New Development
- Illicit Connection and Illegal Discharges
- Education and Outreach
- Reporting

1.5 Program Areas Not Evaluated

The following areas were not evaluated in detail as part of the program evaluation:

- Wet-weather monitoring program and monitoring program details (e.g., sampling location, types, frequency, parameters).
- Other NPDES permits issued to the co-permittees (e.g., industrial or construction NPDES stormwater permits).
- Inspection reports; plan review reports, and other relevant files. The program evaluation team did not conduct a detailed file review to verify that all elements of the Program were being implemented as described. Instead, observations by the evaluation team and statements from the co-permittees' representatives were used to assess overall compliance with permit requirements. A detailed file review of specific program areas could be included in a subsequent evaluation.

1.6 Program Areas Recommended for Evaluation

The evaluation team recommends the following additional assessments:

- A review of the new development planning program implemented by the co-permittees, including implementation of Supplement A and Water Quality Management Plans (WQMPs) after adoption.
- An evaluation of the co-permittees implementing programs developed in compliance with Board Order R8-2002-0011 that were not included in this round of evaluations.

2.0 Program Evaluation Results

This program evaluation report identifies potential violations, program deficiencies, and positive attributes. This report is not a formal finding of violation. Potential violations are areas of concern that Regional Board staff should review to determine whether a violation has occurred. Program deficiencies are areas of concern for successful program implementation. Positive attributes indicate a co-permittee's overall progress in implementing the Program. The evaluation team identified only positive attributes that were innovative and exceptional (beyond minimum requirements). Some areas were found to be simply adequate; that is, not particularly deficient or innovative.

The evaluation team did not evaluate all components of each co-permittee's Program. Therefore, the co-permittees should not consider the enclosed list of program deficiencies a comprehensive evaluation of individual program elements.

The most significant program deficiencies and positive attributes identified during the evaluation are noted in the Executive Summary and are identified with text boxes in the following subsections.

2.1 Findings Common to All Three Cities

2.1.1 Evaluation of Program Management and Effectiveness

Potential Permit Violation:

- *The cities are not taking adequate steps to comprehensively evaluate program effectiveness.*

The cities are not taking adequate steps to evaluate program effectiveness more comprehensively and go beyond the collection of water quality monitoring data. The current annual reports summarize past activities but do not provide detailed analysis to evaluate those activities. The cities should use the annual report to analyze not only *what happened* but also *why* it happened and *what needs to change* in the future to improve the Program. Ultimately, this evaluation will help the cities to improve implementation of the Program and help document water quality improvements.

For additional information on program evaluations, the cities should review the presentations from the November 14, 2003, meeting of the California Storm Water

Quality Association. That meeting focused on MS4 program effectiveness and how MS4s can document such effectiveness. The presentation materials are available at <http://www.casqa.org/swqtf/presentations.htm>. An additional resource is *A Framework for Assessing the Effectiveness of Jurisdictional Urban Runoff Management Programs* developed by the San Diego Municipal Storm Water co-permittees. A copy of the report is available at http://www.projectcleanwater.org/pdf/CoPermittees/assessment_framework_final.pdf

Deficiency Noted:

- *The cities have not developed city-specific local stormwater management plans.*

Although the co-permittees have developed the regional DAMP, they have not developed individual stormwater implementation plans to provide each city with specific direction on the implementation of the Program. Review of the DAMP demonstrated that it is general in nature, providing guidance for the co-permittees but not specific details regarding local implementation. The co-permittees should develop individual stormwater management plans, based on the DAMP's overall guidance and program objectives that describe specifically how the Program will be implemented in each municipality. The cities would benefit from developing individual plans that identify the specific city organization(s) responsible for each activity. The local stormwater management plans should not only identify activities specific to the city but also provide the detailed direction and guidance needed to implement these activities.

As an example, the cities can review the stormwater local implementation plan (LIP) developed by the City of San Clemente for the San Diego Regional Water Quality Control Board at <http://ci.san-clemente.ca.us/Org/Dept/Engineering/WaterQ/wq.htm>. The LIP is the City's local plan for complying with stormwater permit requirements, and it is based on the regional DAMP developed by all permittees in the County. The cities in Riverside County should adopt a similar approach to implementing their stormwater program.

2.1.2 Evaluation of New Development and Redevelopment Program

Potential Permit Violations:

- *It is unclear whether the co-permittees are fully implementing the requirements in the New Development Guidelines (Supplement A to the DAMP).*

Permit provision VIII.A.2 requires each city to implement the BMPs identified in the New Development Guidelines, Supplement A to the DAMP. Supplement A describes "standard practice" BMPs for specific development types. For example, new retail/office center developments are required to implement specific nonstructural and structural BMPs identified in Tables 1 and 2 of Supplement A. One of these BMPs, control of impervious runoff (S1), describes how direct drainage from impervious areas to the street or a storm drain is discouraged and should be avoided. It was not clear from the evaluation that the cities are consistently requiring the BMPs in Supplement A for the development types specified in Tables 1 and 2.

- *The co-permittees lack adequate guidance for reviewing new development project plans to assist with implementation of Supplement A and Water Quality Management Plans (WQMPs).*

The co-permittees have not developed city-specific guidance and procedures for implementing Supplement A and, after adoption, the WQMP requirements. This guidance would include information on who will review project-specific WQMPs and details of each city's review process for project-specific WQMPs. The review of project-specific WQMPs is a complicated and detailed process. A checklist or similar review guidance would help ensure that plan review staff cover all the required elements in the WQMP. The Principal Permittee could develop model program guidance, and individual co-permittees could then customize the guidance for their unique programs and activities.

Two examples of local manuals developed to address post-construction stormwater requirements are available from San Diego County (http://www.sdcounty.ca.gov/dpw/watersheds/land_dev/susmp.html) and the City of Los Angeles (<http://www.lastormwater.org/Pages/partb.htm>).

2.1.3 Evaluation of Public Education and Outreach Program

Deficiency Noted:

- *The cities should develop a more statistically valid survey of public awareness.* Permit provision X.E requires the Public Education Committee to "propose a survey for measuring changes in awareness of Urban Runoff quality as a result of the education program." The co-permittees currently meet this requirement by asking attendees at public events to complete survey forms. The co-permittees should develop a more statistically valid survey using established public survey techniques. An example of a report on a telephone survey of stormwater awareness conducted in San Diego County is available at http://www.projectcleanwater.org/pdf/Carlsbad/public_awareness_03_car_slr.pdf

2.2 City of Corona

2.2.1 Evaluation of Program Management and Effectiveness

See common findings in section 2.1.1.

2.2.2 Evaluation of New Development and Redevelopment Program

See common findings in section 2.1.2.

Deficiency Noted:

- *The City lacks a system to track maintenance of post-construction BMPs.* The City should develop a system to track structural source control and treatment BMPs identified in project plans complying with Supplement A and project-specific WQMPs. Information such as location, type of BMP, responsible party, and operation and maintenance (O&M) inspection and maintenance frequency should be collected to assist the City in ensuring that post-construction BMPs are adequately maintained.

2.2.3 Evaluation of Construction Program

Positive Attribute:

- *The City requires a cash deposit for erosion control BMPs.*

Before issuing a grading permit, the City requires project proponents to post security with the City (Corona Municipal Code 15.36.120). The security must be 100 percent of the estimated costs of erosion control, and at least 25 percent of the required security must be in cash. The remainder of the erosion control security may be a letter of credit, bond, or certificate of deposit. This approach allows the City to quickly correct erosion control problems using the developer's security deposit if the developer does not respond to violations found during inspections.

Potential Permit Violation:

- *The City does not adequately prioritize construction sites.*

Permit provision IX.A.2 requires the City to prioritize construction sites within its jurisdiction as a high, medium, or low threat to receiving water quality. The permit sets a minimum threshold for high priority as any site that disturbs an area greater than 50 acres. The permit also designates minimum inspection frequencies for high-, medium-, and low-priority sites—once every 2 weeks, once a month, and once during the wet season, respectively.

The City has very few construction projects that fall under the high-priority threshold required in the permit. The permit does not specifically define medium- or low-priority construction sites, so the City has defined all construction that is not high-priority as low-priority (that is, no sites are defined as medium-priority sites). The City inspects all construction sites at the medium inspection frequency or greater. The permit, however, requires prioritization of construction sites to be based on factors such as "soil erosion potential, project sites, proximity and sensitivity of receiving waters, history of compliance, and other relevant factors." The City should revise its construction site prioritization scheme so it reflects the construction projects in the City and is a useful tool to help City inspectors prioritize their inspections. For example, the City could tabulate the frequency at which each site is currently evaluated for adequacy of compliance with stormwater requirements. This data would allow the City to better assign priority based on current inspection frequency.

Deficiencies Noted:

- *The City should develop more specific guidance for reviewing erosion and sediment control plans.*

To assist plan review staff in reviewing erosion control plans, the City should develop more specific guidance, such as a checklist or written review criteria. Such guidance would ensure that all staff review plans consistently. The guidance should include good housekeeping BMPs covering concrete washouts, vehicle and equipment fueling, cleaning and repair, sanitary waste, and solid waste management practices,

which are not currently included in erosion control plans. The guidance should also include sediment control during the clearing, grubbing, and rough grading stages, such as the use of sediment traps and sediment basins, erosion and sediment control during active construction (such as the use of straw rolls and sediment traps) and, in general, an effective combination of erosion and sediment controls at all stages of construction.

- *The City should more actively involve building inspectors and public works inspectors in inspections for stormwater compliance.*
Building inspectors and public works inspectors should be more actively involved in conducting inspections for compliance with stormwater requirements. Building inspectors, at a minimum, can correct minor stormwater violations with a verbal warning while on-site, referring serious violations or repeat offenders to the City's primary inspector for stormwater. For public works projects, the City places primary responsibility for stormwater compliance with the contractor. However, the City should also inspect public works projects to ensure compliance with the State's General Construction Permit.

2.2.4 Evaluation of Municipal Facilities and Activities Program

Positive Attributes:

- *The City is developing a sophisticated municipal maintenance work order tracking and reporting system.*
The City is developing a detailed municipal maintenance work order tracking and reporting system called *Crossbow*. This system will eventually allow the City to more accurately track and respond to implementation of the Program. The City is encouraged to integrate stormwater program elements into this system.
- *The City's new corporation yard includes numerous BMPs to address stormwater concerns.*
The City's corporation yard, which the City built approximately 18 months ago, was designed with most activities conducted and materials stored inside the buildings or under cover. The vehicle wash rack is covered and enclosed, and spill kits and mats to cover the storm drain are available near the fueling island.

Deficiencies Noted:

- *The City should increase its storm drain inlet stenciling efforts.*
Although the City has stenciled approximately 500 storm drain inlets, some of them have faded and have not been re-stenciled. The Public Works Department plans to apply more permanent stencils to storm drains. The City is encouraged to stencil all inlets with appropriate stormwater messages and should set a schedule for accomplishing this goal.

- *The City should develop site-specific urban runoff pollution prevention plans for municipal facilities and activities.*

The City has developed an Urban Runoff Plan with BMPs for its facilities, but the BMPs lack specificity for the major municipal facilities and activities. The City should develop site-specific plans similar to industrial stormwater pollution prevention plans for the corporation yard and other municipal facilities with a significant potential to contaminate stormwater runoff. For example, this plan should include a site map showing potential pollutant sources, BMPs, storm drain inlets, and direction of flow. The plan should also identify staff responsible for implementing the BMPs, schedules for inspection and maintenance of the facility and BMPs, and records of maintenance.

2.2.5 Evaluation of Industrial and Commercial Inspection Program

Potential Permit Violation:

- *The City lacks documentation on how it prioritizes industrial and commercial facilities.*

Permit provisions IX.B.2 and IX.C.4 require the City to prioritize industrial and commercial facilities. The permit allows the City some discretion in setting priorities, defining high priorities generally as facilities with “a high potential for or history of unauthorized, non-stormwater discharges.” The City has not documented how it prioritizes industrial and commercial facilities, and it should develop written criteria to be used to classify facilities as having high, medium, or low priority. The criteria should be objective, where possible, with the potential for facilities to be reclassified after an inspection.

Positive Attribute:

- *The City has inspected most of its industrial and commercial facilities and has developed a database to track inspections.*

The City has inspected the majority of its industrial facilities and has started to inspect the commercial facilities. In addition, the City has developed a database to inventory industrial and commercial facilities and track inspections.

2.2.6 Evaluation of Public Education and Outreach Program

See common finding in section 2.1.3.

2.2.7 Evaluation of Illicit Connection and Illegal Discharge Program

Adequate.

2.3 City of Moreno Valley

2.3.1 Evaluation of Program Management and Effectiveness

See common findings in section 2.1.1.

Deficiency Noted:

- *The City would benefit from regular meetings of City department heads to coordinate stormwater efforts.*

The Public Works and Facilities managers do not require the incorporation of stormwater BMPs into the daily routines of their crews. This practice might be due in part to a lack of communication between departments. Regular meetings would reinforce the need to implement stormwater BMPs and would educate department heads about new stormwater concerns and new technologies that might be implemented.

2.3.2 Evaluation of New Development and Redevelopment Program

See common findings in section 2.1.2 above.

Positive Attribute:

- *The City has implemented an annual maintenance charge for the City to maintain post-construction water quality BMPs.*

The City requires that new developments be equipped with water quality ponds and other post-construction stormwater management practices. To ensure that these systems are maintained adequately, the City has developed a legal process by which it assumes maintenance responsibility for these systems. The property owner or homeowner association is legally responsible for maintenance during the initial establishment stage (120 days after installation) and is required to submit as-built planting, irrigation, grading, and drainage plans. After that period, the City performs maintenance on the system and levies an annual NPDES regulatory fee for the service. To track post-construction BMPs, the City developed a spreadsheet and a geographic information system (GIS) of the facilities for which it is responsible, including information such as location, type of practice, property owner, projected maintenance schedule, and actual maintenance costs.

Deficiency Noted:

- *The City lacks a formal, documented plan review process.*

The plan review process is not formalized and is largely the responsibility of a single person. If the rate of development increases or staff turnover occurs, a more formalized process will be needed. Therefore, the City should document its plan review process by developing a review checklist or similar review guidance. This checklist could be provided to developers, as well as City staff, to improve the transparency of the review process and serve as an educational tool.

2.3.3 Evaluation of Construction Program

Positive Attributes:

- *The City has developed and begun to implement the Permits Plus database to schedule inspections based on priority level and results of previous inspections.*
The City has cataloged all construction sites in its jurisdiction and entered them into a tracking database called *Permits Plus*, which is also being used for other applications in the City. The database automatically prioritizes sites based on size (other criteria for prioritizing sites, such as direct discharge to an impaired waterbody, are not automated), and the system schedules inspections based on this priority level. (High-priority sites are inspected biweekly, medium-priority sites monthly, and low-priority sites once during the wet season.) The database also stores information from the inspection form and automatically schedules follow-up inspections based on inspection results (i.e., if a violation is reported). At the time of the program evaluation, this system had just been implemented and had not yet been fully utilized.
- *The City requires the developer or contractor to pay \$250 per construction inspection.*
The City implemented a fee for conducting inspections of construction sites to meet the requirements of the NPDES permit (City Resolution 2003-34). This fee is charged per inspection and generates revenue to support the Program.

Deficiencies Noted:

- *Erosion and sediment control plan review protocols for new development and redevelopment are not formalized.*
Although basic erosion and sediment control practices are required on site plans, a standardized procedure has not been developed for their review and approval. In addition, there is no approved checklist or other guidance to educate developers about the plan requirements for erosion and sediment control and post-construction stormwater management. Coordination among planners, the City's engineers, and inspectors has not been formalized to ensure that adequate plans are developed, approved, and used in the field to maximize the removal of pollutants during construction.
- *Capital improvement projects should use the same criteria as private projects.*
The City's capital improvement projects (CIPs) are inspected using a checklist that differs greatly from the one used for private development projects. A side-by-side comparison of inspection reports by two inspectors at the same site revealed inconsistencies. Most notably, problems with erosion and sediment controls were not adequately detailed on the CIP inspector's forms, and follow-up activities were not noted. In addition, the CIP inspector, who was hired within the past year, had not undergone formal training in erosion and sediment control.

The City should ensure that the training requirement is met and should apply the same standards and inspection checklist to both CIPs and private construction sites. One way to improve consistency would be for the new inspector to receive on-the-job

training by the more experienced construction inspector at both private development and CIP sites.

- *The City should continue with revisions to the enforcement escalation process for construction sites.*

The City's enforcement escalation process, although clearly defined on the construction inspection form, has not resulted in improved compliance at problem sites. The City recently adopted a revised stormwater ordinance that provides the legal authority to impose civil penalties on parties that violate the provisions set forth in the ordinance, the Municipal NPDES Permit, and the NPDES Permit for Industrial/Commercial and Construction Activity. With this expanded authority, the City should be sure to follow through with programmatic changes to improve compliance, such as increasing the frequency of inspections, revising the enforcement escalation process, increasing penalties, and granting code enforcement capabilities to the construction inspector rather than requiring the inspector to refer incidental violations to other city officials.

2.3.4 Evaluation of Municipal Facilities and Activities Program

Deficiencies Noted:

- *The City should include stormwater management-related procedures and standards as contract specifications for all City contractors.*

Contractors hired by the City, for both construction and maintenance activities, should be required to meet the same standards for stormwater control that City crews must meet. One of the most effective means to achieve this end is the contract language. An outline of the standards that need to be met and BMPs that need to be implemented for each project should be included in the contract. This would provide guidance to the contractors as well as an enforceable mechanism for ensuring that acceptable practices are being used. It is also the City's responsibility to audit contractors periodically to verify that they are meeting the requirements set forth in these contracts.

- *The City should develop a standardized employee-training program and provide guidance materials on BMPs for City maintenance crews.*

It was clear that Public Works and Facilities Management staff were not well versed in stormwater management concepts and BMP implementation. In addition to conducting formal training for these employees on stormwater impacts, a manual or other written guidance material that workers can refer to while working in the field should be developed. Such guidance materials could include fact sheets or posters detailing the proper storage and handling of hazardous chemicals, methods for protecting storm drain inlets during minor road work, and ways to identify and report spills or illicit discharges. Materials should be directly relevant to the tasks being performed by each department, which might necessitate developing more than one set of information, each tailored to a different type of task.

- *The City should develop urban runoff management plans for the corporation yard, animal shelter, and fire stations.*

The City manages several facilities that have the potential to adversely affect stormwater quality. Facility-specific plans similar to industrial stormwater pollution prevention plans should be developed. The plans should identify pollutants likely to be generated at each site and specify the BMPs that will be implemented to reduce impacts on the municipal separate storm sewer system (MS4) and receiving waters. Employees at these facilities should be taught periodically about pollution prevention and stormwater management.

The City's corporation yard would benefit from better housekeeping and dust control. There were several instances where fertilizers, small amounts of gasoline, and bags of concrete mix were stored outside in nondesignated areas; these materials should be stored indoors. Also, chemically treated logs, although covered by a tarp, were stored directly on the ground, which could contaminate runoff flowing through the storage area. These logs should be stored indoors (there was a large roofed area that could accommodate these materials) or on pallets so they will not come into contact with stormwater. The large lot was mostly unpaved and could be a source of excessive dust. In addition, stockpiles of sand and other loose materials were stored on-site and should be monitored for erosion due to rainfall or wind.

2.3.5 Evaluation of Industrial and Commercial Inspection Programs

Positive Attribute:

- *The City has linked the Permits Plus database of industrial and commercial facilities to the Business License database, which is updated daily.*

The City has undertaken an effort to automate many of its services, such as tracking business licenses. The Storm Water Program plans to use the *Business License* database to identify new industrial and commercial facilities that require inspections. Many jurisdictions update their industrial and commercial inventories only annually, but the *Permits Plus* system allows for daily updates. The system is also capable of automatically scheduling initial and follow-up inspections.

Potential Permit Violation:

- *The City lacks criteria for designating priority levels for industrial and commercial facilities.*

The City recently assumed responsibility from the County for industrial and commercial stormwater inspections and has hired a consultant to carry out these tasks. Procedures for prioritizing and conducting inspections to ensure compliance with the permit requirements have not yet been formalized. The City must clearly define criteria for assigning priority levels to industrial and commercial facilities and ensure that inspections are scheduled as specified in Part IX.B.3 of the permit.

2.3.6 Evaluation of Public Education and Outreach Program

See common finding in section 2.1.3.

2.3.7 Evaluation of Illicit Connection and Illegal Discharge Program

Potential Permit Violation:

- *The City needs to develop a septic system program to prevent system failures and to replace systems that have already failed.*

The permit (Part VII.B.) requires that septic systems be inventoried and a procedure be established to control septic system failures that could affect water quality. This task has not yet been initiated. The City should work with local sewer agencies to identify properties that are not connected to the sanitary sewer as a means to develop an inventory. Once this inventory is established, the City can work with other agencies to determine the most appropriate way to assess the impact of septic systems on urban runoff and local waterbodies.

Deficiency Noted:

- *The City should improve coordination with spill responders to ensure that spill information is tracked and reported to state agencies and to assess whether the MS4 or receiving waters have been adversely affected.*

As required in Part VI.B of the permit, City staff must notify the state Office of Emergency Services of a spill or illegal discharge. At the time of the program evaluation, no procedure was in place for spill responders (the Fire Department or HAZMAT team) to notify the Storm Water Program of spills that might affect the MS4 or receiving waters. It is important for the Storm Water Program to be able to assess the impacts of spills on the MS4 both for tracking purposes and for mitigation, if needed. The City should work with spill responders to develop an official procedure for notifying the Storm Water Program of spills. The City should also consider providing education on stormwater and NPDES permit requirements to managers and staff responsible for spill response.

2.4 City of Riverside

2.4.1 Evaluation of Program Management and Effectiveness

See common findings in section 1.2.1 above.

Deficiency Noted:

- *The City should consider using activity and BMP specific language in contract specifications.*

The City contracts out some municipal activities (landscaping and park maintenance). The current contract specifications include general language discussing state standards requiring water quality protection. The City is encouraged to revise or augment the current contract language to include specific stormwater BMPs required by the City to protect water quality.

2.4.2 Evaluation of New Development and Redevelopment Program

See common findings in section 1.2.2.

Positive Attribute:

- *The Industrial Waste Division of the Public Works Department is included in the plan review process to address industrial and commercial wastewater issues.*
In-office interviews with the Industrial Waste Division staff revealed that they are included in the new development plan review process. The Industrial Waste Division is responsible for addressing industrial and commercial wastewater issues associated with the plans (inflow and infiltration, drainage, post-construction BMPs associated with industrial and commercial facilities) and must sign off prior to plan approval.

Deficiency Noted:

- *The City lacks a formal mechanism to assign responsibility and track the maintenance of post-construction BMPs.*
The City has no mechanism to assign responsibility for maintaining post-construction BMPs. The development of a formal maintenance agreement would facilitate the assignment of responsibility for routine maintenance of post-construction BMPs. The City also lacks a mechanism to track post-construction BMPs. Tracking the locations, maintenance schedules, and responsible organizations would help the City to establish a routine maintenance schedule and inspection program for such BMPs.

2.4.3 Evaluation of Construction Program

Potential Permit Violations:

- *The City's construction inspectors lack adequate inspection forms, inspection procedures, and training.*

The City's construction inspectors do not have an adequate construction inspection checklist identifying the site-specific BMPs the City requires. The checklist used on-site lacks specific information to assist in determining compliance, including the evaluation of on-site erosion and sediment control BMPs and BMPs to address construction waste, equipment and material storage, and maintenance. In addition, the daily inspection checklist should note necessary maintenance or changes to BMPs, whether any enforcement action has been taken, and whether the site is covered under the Statewide General Construction Permit. The evaluation team visited three construction sites (Colombia Street, Van Buren Avenue, and Riviera Street) and determined that the construction inspectors lacked consistency from site to site. The City is encouraged to provide additional training opportunities for field staff to make sure that they have the tools and education necessary to ensure that construction sites employ proper stormwater controls. Along with the training, the City should develop formalized written procedures for conducting consistent inspections. The development of formalized inspection procedures would provide inspectors with consistent guidance on adequate BMP installation and maintenance, record-keeping, and enforcement procedures.

- *The City does not adequately identify and prioritize construction sites.*

Permit provision IX.A.2 requires the City to “prioritize construction sites within the jurisdiction as a high, medium, low threat to Receiving Water quality (consistent with the criteria contained in Section IX.A.3).” The City does not have a process for continually updating a construction site list as new projects are added or old projects are completed. Although the City is in the process of using the *Permits Plus* database to track construction sites, the City needs to use the database to develop a dynamic list that is periodically updated to reflect prioritization on active construction in the City. The City should also document the criteria used to prioritize sites as high-, medium- or low-priority sites.

2.4.4 Evaluation of Municipal Facilities and Activities Program

Positive Attribute:

- *The City is developing a GIS database system to track municipal maintenance activities in Riverside.*

During in-office evaluations, City staff explained that they are developing a GIS-based Work Order Management System (WOMS) database. The database will track the current municipal maintenance activities by using City work orders. Items that will be tracked include catch basin cleaning, street sweeping, litter removal, and other activities. The database will be suitable for data collection and, ultimately, annual reporting.

Potential Permit Violations:

- *The City's corporation yard lacked adequate practices to prevent stormwater contamination.*

The evaluation team conducted a site visit to the City's corporation yard at 8095 Lincoln Avenue. The corporation yard lacked basic stormwater practices to ensure control of contaminated runoff. Evaluation of the yard revealed the following stormwater issues:

- Vehicles and equipment stored outside the fleet maintenance shop showed obvious signs of leaks. Drip pans or other controls were not provided for stored vehicles.
- Large spills of oil and miscellaneous fluids were also found in the vehicle parking area. Although some of the spills had been covered with absorbent materials, the materials had not been cleaned up.
- On-site spill kits were not plentiful, visible, or accessible to staff. The corporation yard staff were encouraged to increase the number of spill kits on-site. In addition, the spill kits should be located in areas with a high potential for spills, such as the transformer storage area and fueling area. The spill kits should also be labeled and highly visible to staff.
- Vehicle wash water discharge was identified near one of the corporation yard wash racks. The wash water contained miscellaneous trash and evidence of an

oily sheen. The City staff is encouraged to restrict washing activities to the designated wash racks on-site. Control of non-stormwater discharges should be addressed in the facility's Urban Runoff Pollution Prevention Plan as required in Section XI.N of the municipal permit.

- Approximately fifteen 5-gallon paint containers were found exposed. The City staff was encouraged to properly clean up, cover, and dispose of the containers on a regular basis. Also, trash containers throughout the yard were left open; they should be closed when not in use.
- Stockpiles of street sweeping debris, aggregate, and other miscellaneous materials had not been covered. These stockpiles, as well as the surrounding exposed soil, should have controls to reduce or eliminate dust migration, sediment transport, and erosion. As a recommendation, the City could cover the temporary stockpiles with plastic sheeting and use erosion control blankets for the long-term stockpiles. The city is encouraged to conduct dust-suppression practices on a routine basis through watering or the use of a chemical soil binder.

During the site visit the evaluation team discovered two stormwater facilities, a storm drain inlet, and a concrete-lined trapezoidal channel that showed signs of excessive sedimentation. According to City staff, these stormwater facilities are under the jurisdiction of the Riverside County Flood Control District. The storm drain inlet was at the end of a cul-de-sac within the boundary of the corporation yard. Although the inlet had a sediment filtration system, the inlet had not been cleaned or maintained. Thus the filtration system was inundated with sediment, rendering the system ineffective. The City had recently cleaned out the trapezoidal channel, but the channel lacked controls to prevent sediment from entering. The City staff was encouraged to establish an agreement with the County Flood Control District or other agencies to properly maintain these stormwater facilities on a regular basis.

- *The City's corporation yard lacked a site-specific Urban Runoff Pollution Prevention Plan.*

Section XI.N of the municipal permit requires the City to maintain an updated site-specific Urban Runoff Pollution Prevention Plan. During in-office evaluations, members of the municipal maintenance staff explained that they had not yet developed a site-specific Urban Runoff Plan for the corporation yard. The yard could benefit from a plan similar to an industrial stormwater pollution prevention plan that describes the activities, potential pollutant sources, associated BMPs, training, and responsibilities for the yard. In addition, the plan should specifically incorporate BMPs for the deficiencies identified in the finding above.

- *The City does not have written standards, guidance, or training for the maintenance and inspection of structural stormwater controls.*

The City has not developed standards for the maintenance of stormwater facilities, such as storm drain inlets and stormwater basins. The Public Works Department stated that the Street Division conducts inspections of all the municipal storm drain inlets prior to the wet season. The Street Division is responsible for maintaining the City's jurisdictional storm drain inlets. There is no formal set of procedures on how to

conduct routine inspections and maintenance. The City also lacks a training program to teach its staff appropriate procedures for storm drain inlet maintenance. Training would benefit the City's effort to maintain its municipal storm sewer system consistently and adequately.

2.4.5 Evaluation of Industrial and Commercial Inspection Programs

Positive Attributes:

- *The City has developed a GIS database that tracks routine inspections and other activities conducted by the Industrial Waste Division.*

The Industrial Waste Division of the Public Works Department has developed and uses a GIS database that tracks inspections. The database tracks the history of stormwater inspections, violations, and enforcement at industrial and commercial facilities. The industrial inspectors print out the pertinent history and inspection record before any inspection of facilities for that day. The inspection forms, once completed, are entered into the database. New industrial facilities are entered into the database as they obtain new discharge permits. The locations of the new facilities are placed on a GIS map that shows history, location, and contact information when selected in the GIS database.

- *The City has developed requirements that mobile washers and detailers must meet prior to conducting activities in the City.*

The Industrial Waste Division has developed an authorization program for mobile washers and detailers. According to City staff, mobile washers and detailers are not allowed to conduct washing activities until the City has approved them. The City has developed a formal set of requirements that a mobile washer or detailer must meet to operate within the City's jurisdiction. These 10 requirements include, for example, using equipment and procedures to prevent the discharge of wastewater to the storm drain, conducting cleaning activities that comply with the City's ordinance, and using recovery equipment in accordance with the manufacturer's recommendations. The companies must also demonstrate their activities to obtain final approval. The Industrial Waste Division documents the demonstrations and activities. Once a company is authorized to conduct washing activities within the city's jurisdiction, the City adds the company to the vendor list developed by the City. Currently there are 11 such authorized companies; all non-authorized mobile washers and detailers found conducting washing or detailing activities are subject to enforcement per the City ordinance.

- *The City has developed a comprehensive, very detailed, multiphase training program for industrial inspectors.*

The Industrial Waste Division of the Public Works Department has developed a nine-phase training program for industrial inspectors, which the California Water Environment Association has approved. Each phase of the program must be passed with a 90 percent or better score to move on to the next phase. Although the training program focuses on industrial and commercial wastewater discharges, one of the phases concentrates primarily on stormwater aspects such as erosion and sediment

control, nonpoint source discharges, discharges associated with residential areas, and other stormwater issues.

2.4.6 Evaluation of Public Education and Outreach Program

See common finding in section 1.2.3.

2.4.7 Evaluation of Illicit Connection and Illegal Discharge Program

Adequate.

Assessment Report on Tetra Tech's Support of California's MS4 Stormwater Program

Acknowledgments

This report was prepared under US EPA contract number EP-C-05-046, Work Assignment 0-22 and provides an assessment of support Tetra Tech provided to U.S. EPA Region IX and the State of California from July 2001 to July 2006 under several different contracts. The lead author of this report was John Kosco with support from Martina Keefe and Christy Williams.

For questions about this assessment report, please contact John Kosco, Tetra Tech, at John.Kosco@tetratech-ffx.com.

6.5 Provide Guidance on Developing Measurable Goals	23
Appendix A. MS4 Audits Conducted by Tetra Tech in California, July 2001 – July 2006	24

1.0 Introduction

Tetra Tech, Inc. (Tetra Tech) has supported the California State and Regional Water Quality Control Boards with implementation of the MS4 stormwater program since July 2001 under and EPA Region 9 contract. This support has largely consisted of on-site audits of municipal separate storm sewer system (MS4) programs, along with training and special projects. Tetra Tech has completed 36 MS4 audits in the state that addressed 122 permittees. Special projects have included an evaluation of post-construction development standards, review of a series of stormwater Phase II stormwater management plans (SWMPs), MS4 permit development, and evaluations of stormwater monitoring programs.

Information and data collected during these activities were compiled and disseminated to EPA Region 9, the State Board, and the Regional Water Quality Control Boards through audit reports, progress reports, and presentations to the California Stormwater Quality Association, and telephone conversations with regulatory staff. Prior to this report, Tetra Tech had not performed a holistic analysis of information collected during MS4 audits to identify broader trends, lessons learned, and opportunities for advancing these regulatory programs. This report is intended to do the following:

- Describe MS4 audit procedures
- Discuss special projects completed
- Present an analysis of the MS4 audit findings

The focus of this report is on summarizing the work that Tetra Tech has performed to assist EPA Region 9 and California in assessing the compliance status and quality of MS4 stormwater programs throughout the state. The report also includes a discussion of lessons learned from conducting the MS4 audits and provides some brief recommendations for improvements to California's MS4 stormwater program.

EPA Region 9 has placed copies of the MS4 audit reports on their web site at <http://www.epa.gov/region9/water/npdes/ms4audits.html>. This web site also includes a link to a series of stormwater case studies that describes how MS4s have implemented specific aspects of the stormwater program.

1.1 Purpose and Goals of an MS4 Audit

MS4 audits are conducted to address several goals. These goals, discussed further below, include determination of compliance status, providing assistance with permit issuance or renewal, developing Phase II stormwater management programs (SWMPs), and assessing pollutants of concern and assigning wasteload allocations.

Determining Compliance Status

The principal goal of an audit is usually to assess the compliance status of a permittee with respect to its NPDES MS4 permit and SWMP. Where

NPDES permits and SWMPs are specific (e.g., inspect construction sites monthly), then determining compliance status is straightforward. When NPDES permits and SWMPs are written more generally (e.g., retrofit flood control BMPs where applicable), then compliance can be more subjective. If previous audits found permittees to be noncompliant, follow-up reviews might be performed to determine whether issues resulting in permit violations areas for program improvement were addressed adequately.

Assisting with Permit Issuance or Renewal

Tetra Tech has performed audits of municipalities in advance of permit renewals to identify areas of the permit that might require further clarification, detail, or refinement. The audits are especially helpful in opening a dialog between permittees and the Regional Water Quality Control Board (Water Board) about the meaning of specific permit language or the intended goal of an individual requirement, for example. On-site program audits also can be helpful after the issuance or renewal of a permit to address implementation questions and clear up potential misunderstandings about the nature and intent of the permit requirements.

Assisting with Phase II SWMP Development

Tetra Tech has performed audits of Phase II MS4 stormwater programs in part as a compliance assistance tool to correct deficiencies in permittees' SWMPs at an early stage of the program. Phase II municipalities are relatively new to the stormwater permitting world and can benefit from the combined knowledge and experience of the auditors, EPA, and Water Board staff, as well as from *lessons learned* from Phase I municipalities who have been implementing the program for more than a decade.

Assessing Pollutants of Concern and Assigning Wasteload Allocations

Where waterbodies have been determined to be impaired for pollutants that are commonly found in urban stormwater, TMDLs are developed and wasteload allocations assigned to dischargers of those pollutants, including MS4 stormwater programs. Therefore, it is helpful to identify and assess the effectiveness of the activities and best management practices (BMPs) of each MS4 stormwater program in the watershed. This assessment can assist the Water Board in assigning wasteload allocations that are appropriate for each stormwater discharger.

1.2 Benefits of an MS4 Audit

In addition to the goals listed above, numerous ancillary benefits are achieved through the audit process, both for the permittee and the Water Board. These include the following benefits:

- Three days discussing the details of the stormwater program foster stronger coordination and improved working relationships between the Water Board and permittees
- In-depth examinations of permit requirements and program elements yield greater understanding by the permittees of expectations and permit requirements
- Audits provide an opportunity to clarify any misunderstandings in the permit requirements or SWMP
- Direct contact with permittee staff yields improved Water Board knowledge of permittees' operations, priorities, constraints, and challenges faced when implementing a municipal stormwater program

1.3 Roles of Tetra Tech, the Water Board, and EPA

For the past 5 years, Tetra Tech has been assisting the state of California and EPA Region 9 with MS4 stormwater audits. These audits have included large cities, small towns, counties, port authorities, and a California Department of Transportation (Caltrans) district program. Audits covered both Phase I programs and a few Phase II programs, as well as new Phase II programs throughout eight of the Water Board regions. Tetra Tech has enjoyed a strong, effective relationship with Water Board, State Water Quality Control Board, and EPA Region 9 staff.

Typically, Water Board staff members select the programs to be audited; however, Tetra Tech has assisted in making this determination when requested. Once the programs are selected, Water Board staff work with Tetra Tech to determine what type of audit is needed and if any program component focus is necessary. Audit logistics are coordinated with MS4 staff by both Water Board staff and Tetra Tech. Often Water Board staff members participate in the audits as well.

Tetra Tech staff generate audit reports. These reports are subject to rigorous internal Tetra Tech quality assurance protocols before being sent to the Water Board and EPA Region 9 for review and comment. Any requested changes are made, and the reports are then submitted to the Water Board for distribution to the MS4s audited.

2.0 Tetra Tech MS4 Stormwater Audit Approach

2.1 MS4 Audit Preparation

Selecting Permittees

Tetra Tech staff work with Water Board contacts to maximize the value to be gained from each audit. For example, auditing one-fourth to one-half of the permittees covered under a single permit can be very useful in determining the *big picture* of the MS4 program. Of course, an audit of a specific MS4 is sometimes necessary to determine individual compliance with a permit.

Determining Audit Focus

Once the Water Board determines which programs are to be audited, the type of audit must be determined. A component-specific audit focuses on a specific stormwater program area, such as construction activities or new and significant redevelopment. This type of audit is especially helpful if the Water Board has specific concerns about implementation of a particular component (i.e., National Pollution Discharge Elimination System [NPDES] inspections of construction sites

Advance Preparation

- Select permittees
- Identify audit focus
- Organize logistics
- Review documentation
- Hold conference call

To prepare in advance of an audit, Tetra Tech works with RWQCB staff to identify which permittees will be audited and which topics will be covered. Then Tetra Tech organizes logistics with the permittee contacts and obtains and reviews permits, annual reports, SWMPs, and other relevant documents. Tetra Tech then holds a conference call to brief all parties about the purpose and details of the audit and to answer questions about the audit and logistics.

within the MS4 revealed a high degree of noncompliance with the MS4's construction requirements).

In contrast, a comprehensive audit addresses all the generally accepted primary stormwater program areas (i.e., program management, municipal activities, construction, post-construction, industrial/commercial, illicit discharge detection and elimination, and public education/participation). The intent of a comprehensive audit is to assess the MS4's entire program and possibly identify specific areas or issues that might require a more detailed, component-specific audit in the future.

A third type of audit, which Tetra Tech has not yet performed, is a program compliance screening. This type of audit is composed of a basic interview with the MS4 SWMP coordinator or main contact with the program. A program compliance screening could be an efficient and cost-effective method for getting a basic impression regarding the compliance status of the program. This type of review might be the precursor to an in-depth compliance audit at a later date.

MS4 Audit Logistics

The number of permittees and the type of audit determines the logistics necessary to conduct the audit. Tetra Tech staff typically work with Water Board staff and primary MS4 contacts in setting up the audit dates, developing the schedule, identifying meeting places, and creating the audit teams. Depending on the type of audit and size of the program, one to two auditors are necessary for each permittee being audited. Tetra Tech typically organizes a pre-audit conference call 1 to 2 weeks before the audit and includes the audit teams and all interested contacts at the MS4s. Tetra Tech and the Water Board review the schedule, the audit process is explained, and any questions are answered.

Materials to Review before the Audit

Tetra Tech typically reviews the following information before conducting an on-site audit:

- MS4 permit
- Stormwater Management Plan document
- Latest annual report
- Water Board correspondence with the permittee
- Water Board inspections within the MS4
- Permittee Web sites
- Legal authority (i.e., ordinances, memorandums of understanding)

Conducting the Audit

- Kickoff meeting
- Staff interviews
- Inspector evaluations
- Maintenance yard inspection
- Outbrief

On the first day of the audit, Tetra Tech leads a kickoff meeting, providing an overview of the agenda and facilitating introductions. Tetra Tech then interviews staff regarding specific SWMP activities, accompanies inspectors in the field, and inspects the permittee's primary maintenance yard.

Once the interviews and site visits are complete, Tetra Tech provides a brief overview of the positive program elements and program deficiencies seen during the audit. This allows the permittees to provide feedback and clarification directly and in a timely manner. When multiple permittees are audited during the same week, Tetra Tech holds a joint outbrief so the permittees, Regional Board staff, and EPA staff can hear what the other permittees are doing.

If this information is not available prior to the audit, Tetra Tech staff members obtain it during the audit for consideration and review using the audit process.

MS4 Program Audit Guidance

For the State Board's Water Training Academy, Tetra Tech developed a 2-day course and training manual on *Conducting Audits of Municipal Storm Water Programs*, June 2004. Tetra Tech uses this manual to prepare for and conduct audits in California. The manual was developed to assist state and EPA NPDES permitting authority staff in assessing the compliance and effectiveness of Phase I and Phase II MS4 programs.

2.2 Conducting the MS4 Audit

Depending on the size of the MS4 area, the scope of the SWMP, and the type of audit to be conducted, Tetra Tech requires a maximum of 3 days for a comprehensive, in-depth office and in-field program audit.

Kickoff Meeting and Audit Overview

Tetra Tech auditors prefer to organize a *kickoff* meeting at the start of the audit. The kickoff is typically held separately with each permittee. An audit overview is given and any remaining questions are asked and answered by all parties. The logistics are reviewed and the audit teams are introduced.

Audit Process

Approximately 2 to 4 hours are necessary for an adequate in-depth office audit of each program component. The office audit consists of interviews with essential staff and a review of applicable documents. For example, when auditing the construction component of an MS4 program, Tetra Tech staff reviews ordinances, plan review checklists, any relevant guidance or BMP specifications used, and 3–5 approved and pending erosion and sediment control site plans.

In addition, 4 hours per component (e.g., construction, industrial/commercial) is necessary to audit inspection staff in the field. Tetra Tech staff accompany MS4 inspectors to determine their understanding of the MS4 permit, ordinances, and required stormwater BMPs.

Outbrief

Tetra Tech staff perform an outbrief at the conclusion of each audit to present a tentative summary of findings from the audit. Tetra Tech staff are careful to caveat all findings as preliminary at that time subject to change on the basis of further review of audit materials, permit or SWMP and consideration by Water Board staff.

2.3 MS4 Audit Reporting

Documenting MS4 Audit Findings

After the audit is completed, Tetra Tech staff review all notes and supporting information then write a report summarizing all findings. The findings are divided into three categories: (1) permit violations, (2) deficiencies, and (3) positive or commendable program elements. Permit violations are areas where the audit found the permittee not in compliance with a specific permit requirement or SWMP commitment. Use of the qualifier *potential* is used depending on the severity of the violation.

After an MS4 audit report is developed, the Water Board typically distributes the report to the permittee(s) audited with a cover letter summarizing the findings of the audit and any enforcement action being taken or corrections required.

Using Photographs

Tetra Tech staff sometimes use photos to highlight issues on-site that could lend credence to an issue described in the MS4 audit report or to help recall conditions at the sites visited. For example, stormwater problems at a municipal maintenance yard should be documented with photos to provide additional documentation of problems.

After the Audit

- Prepare the report
- Follow up if needed
- Review and comments
- Distribute final report

Once back in the office, Tetra Tech prepares the report, summarizing key findings and providing examples of model programs where appropriate. If needed, Tetra Tech contacts permittee staff to clarify any ambiguities. The report is then submitted to the RWQCB and EPA for review and comment. A final version is then sent via the RWQCB to the permittees.

3.0 Special Projects

Tetra Tech has conducted a number of special projects for the Water Boards that do not fit in with a typical MS4 audit. A summary of these projects is provided below.

3.1 Los Angeles Construction Inspections

For the Los Angeles Water Board, Tetra Tech conducted a series of 31 NPDES compliance inspections at construction sites primarily in Santa Clarita and Simi Valley. Over half the construction sites were residential development projects, with the average site size approximately 10 acres. Tetra Tech inspectors reviewed the stormwater pollution prevention plans (SWPPPs), inspected BMPs on-site, and documented their inspection findings in an inspection report and photo log.

3.2 Review of Post-Construction Development Standards Implementation

To assist the associated Water Board, Tetra Tech conducted audits to determine the implementation of post-construction development standards in three different permit geographic areas—Los Angeles Region (CAS004001, Board Order No. 01-182), Ventura County Region (CAS004002, Board Order No. 00-108), and the San Diego Region (CAS0108758). The primary goal of each audit was to determine the status of each permittee's implementation of the post-construction controls permit requirements. Secondary goals included collecting program implementation information that could be used by the Water Board to compile a model or *recommended* post-construction program and verifying the plan review process itself, collecting information for permit reissuance, and providing assistance to the permittees in implementation of the post-construction requirements. Each permittee was assessed regarding overall success in meeting post-construction conditions and requirements contained within each permit, with a focus on how each permittee reviewed, approved, and implemented the requirements for individual development projects.

The Los Angeles report summarized the findings from the four permittees audited, described the type of development planning program (or post-construction program) recommended by the Water Board, and described recommendations for conducting future SUSMP program reviews. The Water Board used this report to describe to the other 80+ MS4 permittees in the Los Angeles program not audited what type of development planning program they should implement.

3.3 Review of Phase II SWMPs

In June 2005 Tetra Tech audited two Phase II MS4 SWMPs—the cities of Napa and Petaluma. Each SWMP was audited for compliance with permit conditions and implementation of the six minimum measures:

- Public Education and Outreach
- Public Participation/Involvement
- Illicit Discharge Detection and Elimination
- Construction Site Runoff Control
- Post-Construction Runoff Control
- Pollution Prevention/Good Housekeeping

The goals of the audit were to review the overall effectiveness of the program, identify and document positive elements of the program that could benefit other Phase I and Phase II municipalities, and identify program areas for further review by the Water Board.

Each audit took approximately 2 days and resulted in a report of findings that was divided into program deficiencies with recommendations and positive attributes.

Tetra Tech also reviewed approximately 14 city/county stormwater Phase II SWMPs, and over 50 school district stormwater Phase II SWMPs.

3.4 City of Salinas Phase I MS4 Permit Development

In September of 2003 Tetra Tech developed a draft permit and fact sheet for the city of Salinas to regulate stormwater discharges from the MS4. The draft permit package was written in conjunction with the Central Coast Water Board. The permit and fact sheet included the following 10 components:

- Development of a stormwater management plan
- Development of an annual work plan
- Determination of legal authority
- Construction site management
- Development standards
- Commercial/Industrial facilities
- Municipal maintenance
- Illicit discharge detection and elimination
- Public education and participation
- Assessment of program effectiveness

To facilitate developing the permit and fact sheet, Tetra Tech performed an audit of the city of Salinas to identify program areas that required more detailed requirements and direction.

3.5 Stormwater Monitoring Program Evaluations

Tetra Tech has evaluated the monitoring programs of two MS4 programs in California—the Santa Clara Valley Urban Runoff Pollution Prevention Program (SCVURPPP) and San Diego County. Tetra Tech supported the California Water Boards (San Francisco and San Diego) in their assessment of permit-required monitoring activities, reporting, and continuity in the long-term monitoring plan for these two MS4 programs:

The SCVURPPP assessment and evaluation included detailed review of monitoring plans and reports for consistency and compliance with permit requirements and continuing initiatives, as well as for responsiveness to specific requests and requirements of the Water Board. The purposes of this evaluation were to evaluate the overall monitoring program components and their respective contributions toward satisfying the requirements of the permit (CAS029718 and Board Order No. 01-024 and 01-119) and to evaluate the current implementation status of the multiyear monitoring plan with respect to the overall purposes of the monitoring program: to characterize drainage areas and stormwater discharges; assess existing or potential adverse impacts on beneficial uses; identify potential pollutant sources; and collect data that will assist in the evaluation of the effectiveness of the overall stormwater pollution prevention program. Other goals of this evaluation included reviewing the overall effectiveness of the monitoring program relative to the permit goals and requirements, identifying strengths of the program that could benefit other Phase I and Phase II municipalities, and identifying weaknesses in the program that might prevent satisfaction of permit requirements.

The San Diego monitoring program evaluation was conducted differently in that the following two specific requests were presented to the evaluation audit team:

1. Review the existing monitoring program and proposed changes for comparison with the recommendations included in the Model Monitoring Program for Municipal Separate Storm Sewer Systems in Southern California (Model Monitoring Program, or MMP)
2. If appropriate, identify a suite of recommendations that could improve the proposed monitoring program but were not specifically included in the proposed changes

A report was generated to address these requests and was organized into four sections: (1) brief overview of the MMP, (2) brief overview of the current monitoring program and proposed changes, (3) broad recommendations for the San Diego monitoring program, and (4) detailed analysis of current and proposed monitoring program adherence to the MMP.

3.6 Stormwater Training

Tetra Tech developed three 2-day stormwater training courses for state water quality staff as part of the State Water Training Academy. The courses were intended to instruct the staff on all aspects related to managing, reviewing, auditing and issuing municipal stormwater permits. These courses were developed and taught in the first half of 2004 and covered the following topics:

- Reviewing Stormwater Management Plans
- Conducting Audits of Municipal Stormwater Programs
- Municipal Stormwater Permit Writer's Course

Each course was presented by two Tetra Tech stormwater experts, and consisted of a series of modules covering specific program topics, examples, and photographs. Exercises were also included, and ample discussion time was allotted for attendees. In addition to development of the course materials, Tetra Tech also developed an *MS4 Audit Guide* as a reference for the municipal audit course.

4.0 MS4 Audit Analysis

Tetra Tech has audited 84 different MS4 permittees during the past 5 years. These permittees are covered by 23 different permits from eight of the nine Regional Water Boards and one statewide permit issue by the State Board. Most audits were program-wide audits, but some assessed only certain program components. Tetra Tech performed stormwater audits of small municipalities (e.g., Walnut Grove) and of very large urban areas such as Orange County. Several nontraditional MS4s have also been audited such as Caltrans District 5 and the Sonoma County Water Agency.

Table 1: Summary of Phase I MS4 audits performed by Tetra Tech

Permit no.	Permit name or sole permittee	Water Board	Co-permittees	Co-permittees audited ¹	Program components audited

4.1 Summary of Positive Findings

In summary, many permittees have found unique and notable ways to implement aspects of their stormwater programs. Even small programs have invested creativity, staff time, and capital into building strong procedures and practices. Some of the key positive elements to highlight include

- Effectively using technology to organize data and schedule day-to-day activities
- Involving multiple stakeholders in stormwater decision making (e.g., interdepartmental, elected officials, members of the public) using stormwater committees
- Developing concise, transparent, enforcement escalation procedures to address stormwater-related violations
- Focusing BMPs and activities to address pollutants of concern that are specific to local water quality problems
- Allocating staff efficiently, either by training staff from other departments to address stormwater concerns as part of their work or by dedicating one or more positions solely to stormwater compliance
- Actively tracking and assessing progress using measurable goals and performance standards

The following are 10 positive findings that have recurred in multiple audit reports. They are not ranked because they had nearly the same frequency of incidence.

Using GIS to track the location of projects, priority facilities, inspections, and illicit discharges

Many permittees are using a geographic information system to geo-locate potential and actual sources of illicit discharges, which allows staff to target resources and educational efforts most effectively.

Using well-organized (often electronic) methods to track and document inspection and enforcement activities

Effective tracking and documentation is not only crucial to developing the annual reports, but is absolutely necessary to effectively follow up on noncompliance activities. Reinspections must be conducted in a timely manner, and enforcement actions must be issued according to an established timeline. These activities are best tracked using a database or time management software. Some MS4s are able to effectively track these activities using hard copy files, but an electronic system typically works best to remind staff of important deadlines. In addition, very effective tracking systems allow staff to geo-locate noncompliant sites using addresses or GIS.

Performing routine dry-weather inspections of outfalls

All permits issued in California do not require that permittees conduct dry-weather inspections; however, the Tetra Tech audit teams feel that they are a valuable illicit discharge detection tool. The appropriate location and necessary frequency of the inspections vary among permittees on the basis of land uses, size of the MS4, *hotspots* for illicit dischargers, or other factors.

Implementing exemplary public education programs

Permittees are required to educate the general public about stormwater issues; however, several MS4s that were audited had implemented exceptional educational efforts. The audit teams

especially recognize those that are based on pollutants of concern, behaviors of concern, are assessed regularly for effectiveness, and carefully consider the method of delivery according to the desired audience.

Using enforcement response plans to respond to illicit discharge reports

Permittees are typically required to *eliminate illicit discharges*, however, few develop an approved enforcement response plan (ERP) to consistently deal with discharge cases. It is critical that permittees have a documented protocol for the receipt of reports, investigation and follow up, and the issuance of enforcement actions. Some MS4s modify existing ERPs, such as those developed for pretreatment violations or code enforcement.

Using stormwater committees to manage various aspects of the stormwater program

This finding describes committees that are composed of representatives from each of the co-permittees or of staff members from various applicable departments within the same MS4. Regardless of whether the permit covers multiple permittees, managing an MS4 stormwater program generally requires the cooperation of many different departments or agencies. Even in small MS4s, the stormwater coordinator will typically communicate with other departments or contractors to implement various programs. A central committee or task force helps to encourage ownership in the program by various departments, facilitate the necessary reporting, assist in the education of the necessary staff people, and establish a responsible party or contact person from each affected department or agency.

Dedicating staff members solely to inspect construction sites or industrial facilities for stormwater compliance

While it is often impossible for some MS4s to dedicate an inspector to stormwater issues, some MS4s have budgeted for this level of staffing. Typically, having staff dedicated to stormwater issues increases the frequency of project and facility inspections, improves the level of follow up for noncompliance, and improves facility compliance because of the heightened level of technical assistance and oversight provided by the inspector.

Targeting stormwater resources and activities to address pollutants of concern

Most MS4s have limited resources to dedicate to stormwater programs; therefore it is critical that funding and staff time are targeted appropriately. The audit team commends MS4 stormwater managers for proactively implementing programs that address specific pollutants of concern (i.e., 303(d) listed pollutants) and the associated behaviors of concern such as how the public handles pet waste. While general stormwater awareness is important (i.e., stormwater is not treated), to make real progress toward measurable stormwater goals, it is important to focus resources on the most important water quality issues.

Using measurable goals or other performance standards to assess the effectiveness of the program and compliance with the permit

All Phase I MS4 programs are required to assess the effectiveness of the SWMP components; however, many permits in California do not specify that official measurable goals be developed and assessed as is required of Phase II MS4s. Some permittees audited, however, have established stormwater management plans with appropriate goals or standards and regularly assess progress toward meeting those goals. These types of goals are essential in assessing the effectiveness of individual program components and the program in general. Being able to

quantify progress is important not only to the permitting authority, but to the permittee itself to justify budget requests, staffing requirements, and the like.

Using inspectors from other departments to monitor compliance with construction and industrial/commercial stormwater requirements

Often, inspectors from various departments or agencies within an MS4 will visit a construction site or industrial/commercial facility for different reasons. For example, a restaurant will be regularly inspected by the health department for food-related requirements and a pretreatment inspector will inspect the grease trap in the kitchen to determine compliance with source control regulations designed to protect the wastewater treatment plant. It is important that these inspectors be educated about stormwater issues to act as additional *eyes and ears* for the stormwater program during their regular inspections. Or if the MS4 does not have dedicated stormwater inspectors, these existing staff could be used to monitor stormwater compliance at the industrial/commercial facilities they regulate or at additional facilities as necessary. The same concept applies to the various inspectors that visit a site during active construction. Some MS4 programs train grading, right-of-way, electrical, plumbing, or other inspectors in basic erosion and sediment control principals to ensure that stormwater issues are being monitored during all phases of construction.

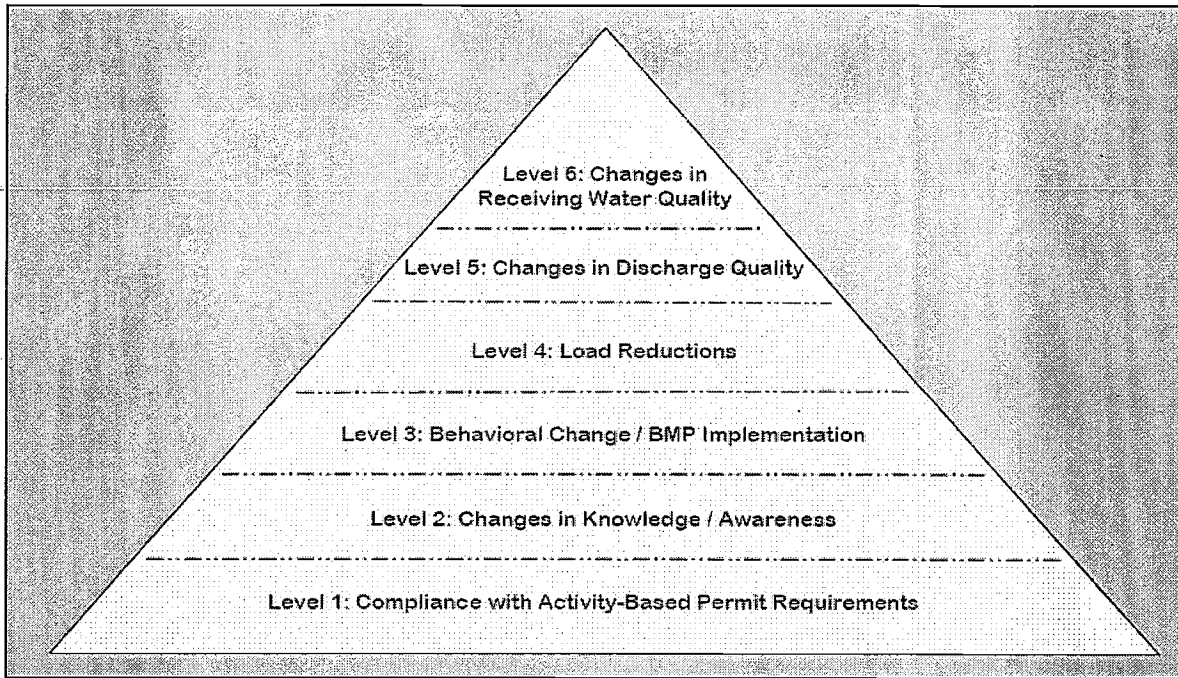

4.2 Innovative Approaches

Tetra Tech has observed a number of MS4 programs using new or innovative approaches to stormwater management. A few of these innovative approaches are summarized below.

Measuring the Effectiveness of Stormwater Programs

Many stormwater Phase I permittees analyze water quality samples and report the data, but are unable to determine whether their stormwater program is effective in protecting and improving water quality. In order to address the question of how effective MS4 programs are, the San Diego co-permittees formed a program effectiveness assessment workgroup to develop a regional approach to assessing the long-term effectiveness of municipal stormwater programs in San Diego County. The workgroup developed a *Framework for Assessing the Effectiveness of Jurisdictional Urban Runoff Management Programs* (the *Framework*), and a *Baseline Long-Term Effectiveness Assessment*. Both of these documents are available at http://www.projectcleanwater.org/html/wg_assessment.html. The workgroup is also coordinating closely with the California Stormwater Quality Association (CASQA) as it addresses effectiveness assessment on a statewide level.

The *Framework* describes six levels of targeted outcomes that municipalities can use to measure their efforts (illustrated below). The higher levels provide a more direct link to water quality improvements, but are much harder to measure. Municipalities must develop a plan that takes into account all levels of targeted outcomes in order to measure and quantify progress. San Diego's effectiveness assessment reports are a large step forward as municipal stormwater programs attempt to demonstrate how their activities protect water quality.

Corporation Yard BMPs

Not every innovation needs to be complicated or expensive. A county in southern California needed to cover a stockpile at their maintenance yard. They found that maintenance staff were not replacing the tarp used to cover the stockpile, so a maintenance supervisor came up with a solution to use a roll-on cover that is typically used on large trucks. Now, maintenance staff can quickly and easily access the stockpile and replace the cover.

Education/Outreach for Construction Operators

Providing clear outreach to construction operators is necessary to ensure they are aware of the local stormwater requirements and what the MS4 expects of them. The City of Coronado developed a simple and graphic brochure was developed for construction site operator. The brochure illustrates the typical construction project within the city and shows what type of BMPs should be installed and where. This gives the operator a clear idea of what the City expects to see at the site in an easy to use format.

4.3 Summary of Program Deficiencies

For the purposes of this report, program deficiencies, potential permit violations, and permit violations all are considered *deficiencies*. Each Regional Water Board determines which, if any, audit finding constitutes a permit violation; therefore, it is too subjective a term to be categorized in this document. The deficiencies noted have been summarized and ranked according to incidence in the reports reviewed, as summarized in Figure 1.

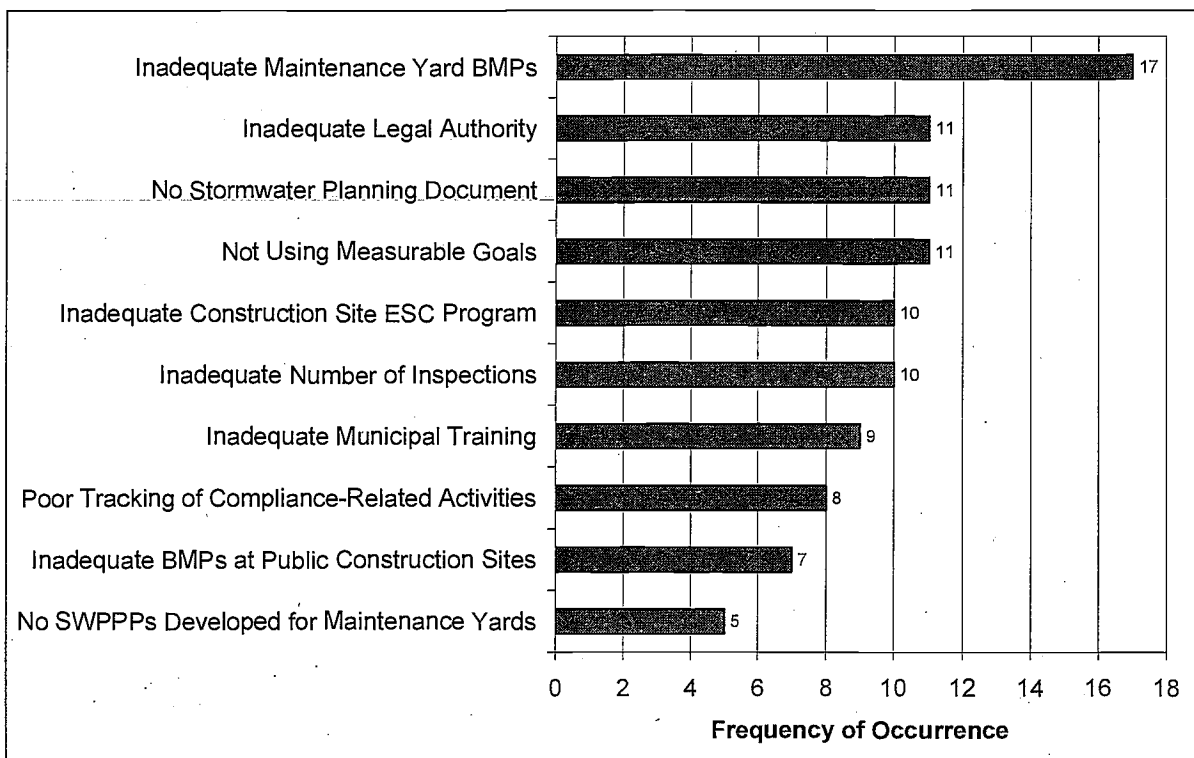

Figure 1. Summary of commonly cited program deficiencies.

Inadequate maintenance yard BMPs

By far the most prevalent program deficiency noted during the audits (17 instances) was the lack of appropriate BMPs at municipally owned and operated facilities, such as corporation or transportation yards. Problems included unprotected storm drains, lack of containment for potentially polluting materials, lack of spill-control measures, and generally poor housekeeping. Often evidence was found of spills that had entered storm drains.

No SWPPPs developed for maintenance yards

Many of the audited permittees had not developed SWPPPs for their corporation yards (5 instances). Typically, these facilities include auto maintenance shops, chemical storage areas, truck-washing facilities, refueling stations, and other facilities and activities that can pose a threat to water quality. Therefore, a plan should be in place that identifies potentially polluting locations and activities, specifies BMPs for each, and outlines spill control and response measures. The SWPPP or similar document should be in place even if the facility is not required to have permit coverage under the industrial stormwater general permit.

No stormwater planning document

Tetra Tech found that several permittees (11 instances) had not developed a stormwater management plan (SWMP) or other document that describes the different activities of the program and includes standard operating procedures and other details. Without a master planning document that lays out current program activities and future goals, it will be difficult for permittees to progress the program in a focused manner. This document also provides a detailed description of the program that state regulators can use to assess compliance, especially if the SWMP is a *living document* that is updated with new program elements and procedures.

Not using measurable goals

One important element that is commonly described in the SWMP but was often lacking in programs audited in California was a clear method for evaluating program effectiveness (11 instances). In many cases, permittees implement their programs and individual BMPs without developing measurable goals, monitoring programs, or other methods to track progress over time. One of the ways in which permittees can show progress is to demonstrate effectiveness, for example, that increased frequency of inspection yielded fewer violations or that field screening results showed fewer *hits* for bacteria the year after a focused effort to eliminate improper connections to the storm drain. Without these measures, permittees cannot know whether their activities are having a positive effect on stormwater quality, nor can they gauge which activities provide the most benefit.

Permittees can also measure program progress by comparing a current year's activities to past years' activities. Tracking and evaluating program data can provide insights into where improvements have been and still need to be made. For example, if after 5 years of program implementation there has been no change in the number or type of violations found at construction sites, a new approach might be needed that focuses on education or that includes increased penalties for noncompliance. If, on the other hand, repeated inspections at a sector of commercial businesses never or rarely yield a violation, the permittee might consider using those resources to target a different business type that is more likely to contribute to stormwater pollution.

Inadequate legal authority

Another common finding (11 instances) is that permittees lack adequate legal authority to implement one or more elements of their program. This could have resulted from a number of factors, including

- Lack of political support from elected officials
- Inability of inspectors to obtain code enforcement capabilities
- Lack of an ordinance that prohibits nonstormwater discharges to the MS4
- The permittee is a nontraditional institution that does not have enforcement authority

Because there are several different causes for this lack of legal authority, each instance would need to be addressed on a case-by-case basis in the context of the permittee's municipal structure, organization, and unique constraints.

Inadequate number of inspections

Many permittees were lax in performing inspections and enforcing their stormwater ordinance (10 instances). These permittees had no or few inspectors dedicated to addressing stormwater concerns, and they did not train inspectors in other departments, such as pretreatment, fire safety, or health department inspectors, to look for stormwater violations.

Inadequate construction site erosion and sediment control program

In some cases (10 instances), inspectors were performing inspections inadequately, using *drive by* inspection techniques that would not identify problems with individual BMPs, whether they be design flaws or poor maintenance. As a result, sites can be *in compliance* even though water quality is not being protected adequately. Better training and more careful oversight of inspectors can help to remedy this quality control situation. It is also important that permittees with multiple inspectors foster consistency in terms of inspection protocols, level of stringency, and types of BMPs that are acceptable. Permittees can team inspectors together from time to time to share knowledge and advice, develop a standardized checklist for all inspectors to use, or develop a BMP standards manual that clearly outlines a permittee's expectations for its inspectors and construction sites.

In addition, several programs had inspectors who were knowledgeable and thorough in their inspection technique but were unable to bring facilities into compliance because they lacked adequate authority to levy fines and other sanctions (see "Inadequate Legal Authority" above).

Inadequate BMPs at public construction sites

Many permittees had separate approval and oversight procedures for private construction projects when compared to procedures for public capital improvement projects. In several cases, this division has led to lax implementation of BMPs at publicly owned construction sites (7 instances). Permittees should hold their own project proponents and contractors to the same standards as private construction operators and developers, not only to maintain compliance with the permit and avoid illicit discharges from public construction sites, but also to set a good example for the regulated community.

Inadequate municipal training

Lack of training for municipal personnel was another common finding (9 instances). Many times when street or parks maintenance crews were observed working in the field, BMPs were either inadequate or absent, and storm drains were unprotected. Permittees either do not offer training to field crews or only provide minimal training that is not reinforced regularly. Stormwater-related training should be offered to all staff involved with spill response, those handling materials that could enter storm drains, and street crews who can spot spills or illicit discharges while they go about their daily routine in the permit area.

Poor tracking of compliance-related activities

Some permittees fail to track their compliance-related activities (8 instances) and, therefore, are unable to demonstrate that such activities were performed, nor can they document the compliance status of industrial facilities or construction sites. Paperwork might be lacking because it is not part of the permittee's protocols, individual inspectors are lax in filling out paperwork or only partially fill it out, or forms are not filed or entered into a database in such a way as to facilitate data retrieval.

A related problem is that the universe of construction sites or industrial and commercial facilities to be inspected is not updated regularly or systematically. Whether permittees track construction activities on the basis of grading permits issued or requests for engineering inspections or other methods, a list of active sites should be maintained at all times. The same is true for industrial and commercial facilities to be inspected—business licenses can be tracked, windshield surveys of commercial areas can be performed, and so on. Having these site and facility inventories allow inspectors to know where to go and how to schedule inspections and budget their time. It also allows permittees to track progress toward achieving one or more measurable goals in terms of the number or percentage of total sites inspected each year.

5.0 Lessons Learned

Over the past 5 years, a number of patterns have emerged from discussions with both state regulators and municipal stormwater permittees. The following is a set of *lessons learned* that can offer opportunities to streamline and improve both NPDES permits and local stormwater management programs.

5.1 MS4 Permit Language Greatly Affects SWMP Development and Compliance

Tetra Tech has found that programs with more specific permit requirements generally result in more comprehensive and progressive stormwater management programs. For example, the more specific permit requirements in the Los Angeles or San Diego MS4 permits require permittees to be more specific in how they implement their stormwater program. Programs with more general stormwater permit requirements, where the emphasis is on implementation of a stormwater management plan, generally did not have as comprehensive a stormwater program.

5.2 Need for Clear Guidance and Direction from the Water Boards

Beyond the NPDES permit requirements, many MS4s do not have clear guidance or direction from the Water Boards on how they should implement specific aspects of their stormwater program. Some municipal programs have developed guidance for specific topics, such as the C.3 new development requirements in Contra Costa County, or the SUSMP requirements in Los Angeles.

One example of where the Water Boards provided more specific direction on an MS4 program area is the November 2003 Development Planning Program Review Report for Los Angeles developed by Tetra Tech and the LA Water Board. The report included a section on a "development planning program recommended by the Water Board." MS4s were told to consider the recommended program as they implement their new development and SUSMP programs.

Providing this additional guidance is particularly effective in areas such as the LA Board where there are too many permittees for the Water Board to audit on a regular basis.

5.3 Communication Provides Many Benefits

Tetra Tech audit staff believe that almost all municipal stormwater programs want to be in compliance and implement effective programs. However, some municipalities stated they did not receive frequent communication and feedback from their Water Board contacts. The MS4 audits conducted with Water Board participation provide an opportunity for permittees and Water Board staff to spend three days together. This often leads to a better understanding of the challenges each face in implementing a stormwater management program and regulating MS4 permit programs.

As an unbiased third party, Tetra Tech can interview staff to clarify program details, while at the same time establish a forum for discussion between the state regulators and permittees. This has been beneficial to the State and to the permittees. Many communities have expressed their appreciation of the feedback that Tetra Tech provides with respect to how their activities measure up to the state's expectations. One city engineer wrote,

I really appreciate the time you spent with us and the feedback and suggestions you were able to provide. As I am sure you can imagine, from a local program standpoint the term "audit" naturally sparks apprehension and curiosity. I believe we all take this program seriously, but having an objective review for the first time gives us an opportunity to benchmark ourselves against the expectations of the RWQCB and outside experts. I can honestly say that your style and approach to the whole process made it a very enjoyable and enlightening experience. As an auditor it would be easy to be critical and judgmental, but instead you use your experience and insight to be helpful and constructive. I can't tell you how welcome that is from our end.

5.4 A Well-Written SWMP Plan is Critical for Compliance

MS4s without a document or plan describing stormwater management program components, implementation mechanisms and responsible parties are more apt to be disjointed, disorganized, and vulnerable to noncompliance, especially if staff turnover is high. Permits should include a requirement that a single planning document or a series of component-specific documents be developed that describe implementation procedures, BMPs, schedules, responsibilities, and goals. This SWMP Plan would also allow state regulators to assess a permittee's procedures through document review in lieu of, or in addition to, site visits.

5.5 Measurable Goals Should Be Outcome-Based

Permittees should be required to develop measurable goals based on the desired outcomes of the stormwater program. These goals should be developed on the basis of the pollutant of concern, sources of the pollutant, behaviors associated with the sources, and the indicator most appropriate to demonstrate a change in those behaviors. For example

Pollutant of concern	Sediment
Source	Erosion from construction sites

Behavior	Construction site operators install and maintain BMPs poorly
Goal	Increase the number of operators who are aware of, understand, and comply with the erosion control regulations and plans
Indicators	(1) percent of contractors in the city who have attended a training (to increase as the program progresses); (2) percent of operators who repeatedly violate regulations (to decrease as the program progresses)

5.6 Annual Reports are not Effective Indicators of Program Compliance

Largely due to the lack of specificity in annual reporting requirements, Tetra Tech has found that the annual reports submitted by Phase I MS4s are not always effective indicators of program compliance. Although annual reports are useful to review before an MS4 audit and should be used to spot compliance “red flags,” they are usually inadequate determine compliance by themselves. This is because, without specific reporting requirements, municipalities are reluctant to voluntarily report non-compliance.

6.0 Recommendations for Improvements to California’s MS4 Stormwater Program

The following brief recommendations, based on Tetra Tech’s past experience in the state, are made to help improve the effectiveness of California’s MS4 stormwater program:

6.1 Continue MS4 Audits and Conduct Targeted MS4 Audits of Specific Program Components

Some MS4s have not been audited yet. These MS4s could be prioritized for audits, along with MS4s for which the Water Boards will soon be reissuing their NPDES MS4 permit. In cases where the Water Board staff is familiar with the program, the audit could be brief and cover only what has changed since the last permit issuance.

Additionally, the Water Boards could conduct targeted MS4 audits of specific program areas. Tetra Tech has already conducted targeted MS4 audits of the new development, or SUSMP, programs in Los Angeles, Ventura, and San Diego Counties. Additional targeted MS4 audits could be conducted focusing on the illicit discharge, municipal maintenance, or construction components of a permittee’s SWMP. Water Boards could select the MS4s and program components to audit based on watershed specific issues, pollutants of concern, TMDLs, or other factors. In addition to determining compliance, the findings from these targeted MS4 audits can also be used to develop guidance from the Water Board on these program components.

6.2 Develop Compliance Tools for Regulators and MS4s

A number of compliance tools should be developed to help MS4s implement the program and help Water Board staff ensure compliance. For example, Tetra Tech has developed an *MS4 Audit Guide* for the state and is currently expanding and revising this guide for U.S. EPA. The *MS4 Audit Guide* will help Water Board staff in conducting MS4 audits, but it also helps MS4 programs conduct a self-assessment to ensure they are complying with their permit requirements.

Additional tools could include a BMP selection guide MS4s would need to use to ensure they were in compliance with the MEP standard. The guide would also be used by Water Board staff to evaluate the adequacy and effectiveness of BMP programs and determine compliance with permit requirements. The guide could include:

- Minimum requirements for BMP siting, sizing and design standards, and operation and maintenance specifications,
- Assessment tools, methods to measure effectiveness, an surveillance and monitoring requirements for each BMP that must be implemented by the permittee to demonstrate compliance, and
- Minimum recording and reporting requirements.

6.3 Develop a Consistent Format for MS4 Permit Language

Presently, the State develops permits on a regional basis, and the level of specificity and individual requirements vary widely. Some permits detail individual BMPs that should be implemented for each program area and include guidance on how and to what extent they should be implemented. This specificity can assist the permittees in knowing how best to meet permit requirements and reduces ambiguity. However, this can result in municipalities implementing substantially similar programs but with significantly different details and requirements.

One factor for the state to consider when writing permit language is to be clear enough to set appropriate standards and establish required outcomes, but still allow permittees to be creative and innovate solutions to stormwater management that are appropriate for their situations. The audits of the past 5 years have shown that each permittee approaches implementation from its own unique perspective and with unique attributes and constraints that sometimes facilitate and other times confound implementation. The *one size fits all* mantra does not apply to MS4 stormwater programs because the ways in which they are implemented depend on each permittee's organizational structure, staff availability, and budget, along with legal constraints and more- or less-favorable political climates. Each MS4 may develop and work toward different measurable goals, but still be able to achieve the required outcome.

However, a consistent format to the MS4 permit and the basic requirements in the permit will provide some statewide consistency to the stormwater program and allow programs to share resources more easily. This consistent format will also require MS4s to be on more of a level playing field as they implement their programs.

6.4 Provide Guidance on Annual Reporting

Often annual reports are the only official communication from year to year between the permittee and the state, so it is important that the report be informative and relevant. Many times

permittees tend to send too much information, and, as a result, state regulators receive huge binders full of hard copy forms and outreach materials that do not provide useful information to assess compliance. Because of the time involved in preparing such large documents, less time could be spent preparing summary information and compiling data that would be useful to assess compliance.

To remedy this, the state could develop a set of guidelines that clearly describe the information they would like included in the report. For example, the following program information is necessary when assessing construction inspection programs:

- Number of active construction sites a permittee needs to inspect
- Number of staff are performing inspections
- Frequency of inspections
- Total number of inspections performed
- Number of violations found and follow-up actions performed

This information allows state regulators to determine if staffing levels are adequate, if inspections are being performed, and if enforcement activities are occurring. Other information, such as a list of “bad actor” operators with violation frequency and other summarized tracking data maintained by the permittee, could be helpful to provide a clearer picture of the permittee’s procedures. Submission of materials such as individual forms or notices of violation would be burdensome for both the permittee and the reviewer and should be discouraged in the guidelines. The information included in the annual report should clearly demonstrate progress towards reaching measurable goals, and therefore may vary by permittee.

6.5 Provide Guidance on Developing Measurable Goals

The state should include guidance on how permittees can develop measurable goals and performance standards so they can track their own progress and share this information as part of the annual report. Permittees will need to tailor their measurable goals to their specific pollutant sources, behaviors, activities, and protocols; therefore, the state should provide examples of the types of quantifiable goals they would consider acceptable in different kinds of situations. For example, the state might want to know how effectively the permittee has been advertising household hazardous waste collection events. The permittee could track attendance at the event from year to year and, if their methods are effective, expect to see a steady increase in first-time attendees (10 percent, for example) over time. Permittees have in the past described measurable goals in non-numeric terms, such as “track the number of first-time attendees at events,” but it is important that there be a numeric target or rate of change incorporated into each goal. This is particularly important for Phase II MS4s under the general permit.

EPA has issued guidance on developing measurable goals that could be referenced by the Water Boards or serve as the starting point for a new guidance (see <http://cfpub.epa.gov/npdes/stormwater/measurablegoals/index.cfm>).

Appendix A. MS4 Audits Conducted by Tetra Tech in California, July 2001 – July 2006

Location	MS4 Audited	Date of Audit
Alameda	Cities of Dublin, Fremont, Hayward, Livermore, and Oakland	November, 2001
American Canyon	City of American Canyon	June, 2005
Bakersfield	City of Bakersfield and Kern County	November, 2002
Caltrans	District 5	July, 2002
Contra Costa	Cities of Antioch, Brentwood, and Oakley	March, 2005
Contra Costa	Cities of Concord, Pinole, Pittsburg, Richmond, and San Pablo	September, 2004
Contra Costa	Cities of Hercules and Pittsburg, Walnut Creek, and Concord, Contra Costa County, and Contra Costa Clean Water Program	May, 2003
Elk Grove	City of Elk Grove	April, 2005
Fresno	Cities of Fresno and Clovis, and the Fresno Metropolitan Flood Control District	January, 2005
Lake Tahoe	City of South Lake Tahoe, El Dorado County and Placer County	June, 2002
Long Beach	City of Long Beach	August, 2001
Los Angeles	LA County and Cities of Glendale, Los Angeles, and Santa Monica. Review of Standard Urban Stormwater Mitigation Plan (SUSMP) requirements.	March, 2003
Los Angeles	Cities of Calabasas, Carson, Glendora, Pomona and Santa Clarita. Review of city's construction program	June, 2004
Modesto	City of Modesto	February, 2004
Napa	City of Napa	June, 2005
Orange County	Cities of Laguna Beach, Laguna Hills, Lake Forest, Rancho Santa Margarita	May, 2005
Orange County	Orange County and Cities of Mission Viejo, San Clemente, and San Juan Capistrano	June, 2003
Petaluma	City of Petaluma	June, 2005
Riverside	Cities of Corona, Moreno Valley and Riverside	May, 2004
Sacramento	County of Sacramento and the Cities of Folsom, Galt, and Sacramento	March, 2002
Salinas	City of Salinas	July, 2003
San Bernardino	Cities of Fontana and Redlands and San Bernardino County	October, 2004
Santa Clara	Cities of Milpitas, Palo Alto, Santa Clara, and Santa Clara County	April, 2005

Location	MS4 Audited	Date of Audit
Santa Clara	City of San Jose and County of Santa Clara	December, 2003
San Diego	Cities of Carlsbad, Chula Vista, and El Cajon	May, 2002
San Diego	Cities of Encinitas, Lemon Grove, Poway, and Santee	April, 2004
San Diego	Cities of Escondido, National City, Oceanside	February, 2003
San Diego	Cities of Imperial Beach, La Mesa, San Marcos, and Vista	October, 2003
San Diego	City of San Diego, County of San Diego	October, 2002
San Diego SUSMP	Cities of San Diego, Carlsbad, Lemon Grove, Chula Vista, Oceanside, National City, Poway, El Cajon, Escondido and San Diego County. Review of Standard Urban Stormwater Management Plans (SUSMPs)	March, 2005
San Diego	Cities of Solana Beach, Coronado, and Del Mar and Port of San Diego	November, 2004
San Mateo	County of San Mateo and Cities of South San Francisco, Foster City, Pacifica, Redwood City, and San Mateo	August, 2002
Santa Rosa	City of Santa Rosa, Sonoma County, and the Sonoma County Water Agency	March, 2002
Stockton	City of Stockton and San Joaquin County	December, 2002
Ventura	Ventura County Flood Control District and the Cities of Ojai, Oxnard, Santa Paula, and Simi Valley	October, 2001
Ventura SQUIMP	Cities of Fillmore, Moorpark, Port Hueneme, Ojai, Oxnard, Santa Paula, Simi Valley, the County of Ventura, and the Ventura County Watershed Protection District. Review of Stormwater Quality Urban Impact Mitigation Plan (SQUIMP) requirements	August, 2004

ATTACHMENT 46

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

REGION IX

75 Hawthorne Street
San Francisco, CA 94105-3901

APR 10 2008

Ms. Tam M. Doduc, Chair
Ms. Dorothy R. Rice, Executive Director
State Water Resources Control Board
1001 I Street
Sacramento, CA 95814

Dear Ms. Doduc and Ms. Rice:

I understand that certain specific provisions of the 2001 Municipal Separate Storm Sewer System ("MS4") permit for the County of Los Angeles have been called into question as going beyond what is required under section 402(p) of the CWA. (Commission on State Mandates, File Nos. 03-TC-04, 03-TC-19, 03-TC-20, and 03-TC-21.) The permit conditions at issue are: 1) the requirements for conducting inspections at industrial and commercial facilities including restaurants and automobile servicing, [Parts 4.C.2.a. and b.] and, 2) the requirement for permittees not subject to the Trash TMDL to locate and maintain trash receptacles at transit stops [Part 4.F.5.c.3.]. California RWQCB, Los Angeles Region, Order No. 01-182, NPDES No. CAS004001 (Dec. 13, 2001). This letter discusses these permit conditions in the context of EPA's expectations for MS4 permits.

Section 402(p) of the Clean Water Act, 33 U.S.C. 1342(p), requires EPA (or authorized states) to issue National Pollutant Discharge Elimination System ("NPDES") permits to regulate the discharge of stormwater from MS4s. Typically, these MS4s are owned and operated by cities and counties. Pursuant to the Clean Water Act, these permits must require the MS4 to: 1) "effectively prohibit" non-stormwater discharges, and 2) "reduce the discharge of pollutants to the maximum extent practicable, including management practices, control techniques and system, design and engineering methods, and such other provisions as the Administrator or the State determines appropriate for the control of such pollutants." 33 U.S.C. 1342(p)(3)(B)(ii) and (iii).

The NPDES regulations require medium and large MS4s to develop stormwater management programs that the permitting authority will consider when developing permit conditions to reduce pollutants in discharges to the maximum extent practicable. Stormwater permitting has generally relied on the use of best management practices ("BMPs"), including both structural and non-structural controls, for achieving compliance with these requirements. The EPA also expects stormwater permits to follow an iterative process whereby each successive permit becomes more refined, detailed, and expanded as needed, based on experience under the previous permit. See, 55 Fed. Reg. 47990, 48052 ("EPA anticipates that storm water management programs will evolve and mature over time."); 64 Fed. Reg. 68722, 68754 (Dec. 8, 1999) ("EPA envisions application of the MEP standard as an iterative process."); Interim Permitting Approach for Water Quality-Based Effluent Limitations in Stormwater Permits (Sept. 1, 1996) ("The interim permitting approach uses BMPs in first-round storm water permits, and

expanded or better-tailored BMPs in subsequent permits, where necessary, to provide for the attainment of water quality standards"). See also, "Evaluating the Effectiveness of Municipal Stormwater Programs" (January 2008)

(http://www.epa.gov/npdes/pubs/region3_factsheet_swmp.pdf). While the standard of "maximum extent practicable" (MEP) allows for flexibility, that flexibility is not boundless and requires some level of vigor. EPA has created a national menu of stormwater BMPs to provide additional guidance concerning appropriate BMPs for stormwater management plans. Other factors to consider in ensuring appropriate controls include "technical feasibility, cost, public acceptance, regulatory compliance, and effectiveness." Building Indus. Ass'n v. State Water Res. Control Bd., 124 Cal. App. 4th 866, 889 (2004). See also "In re-Cities of Bellflower, et al.," SWRCB 2000-11.

At the outset, I note the Los Angeles MS4 permit is a third generation Phase I MS4 permit that should be building upon the experiences from previous permits. Both of the provisions at issue here seem well within a reasonable expectation of controls that reduce pollutants to the "maximum extent practicable." EPA regulations at 40 C.F.R. §122.26(d)(2)(iv) set forth the basic elements to be included in a Phase I MS4's stormwater management program. Subparagraph (A) requires a description of "source control measures to reduce pollutants from runoff from commercial and residential areas that are discharged from the [MS4] that are to be implemented during the life of the permit." Subparagraph (B) requires a program for detection and removal of illicit discharges and improper disposal into the storm sewer, including a program for inspections and enforcement. A program for commercial and industrial facility inspection and enforcement that includes restaurants and automobile facilities, would appear to be both practicable and effective. Such an inspection program ensures that stormwater discharges from such facilities are reducing their contribution of pollutants and that there are no non-stormwater discharges or illicit connections. Thus these programs are founded in both 402(p)(3)(B)(ii) and (iii) and are well within the scope of 40 C.F.R. §122.26(d)(2)(iv)(A) and (B).¹

Similarly, maintaining trash receptacles at all public transit stops is well within the scope of these regulations. Among the minimum controls required to reduce pollutants from runoff from commercial and residential areas are practices for "operating and maintaining public streets, roads, and highways . . ." §122.26(d)(2)(iv)(A)(3). I believe these requirements are also practical and effective.² Moreover, this permit provision is consistent with EPA's national menu

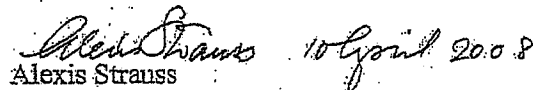

¹EPA's "MS4 Program Evaluation Guidance" (January 2007) envisions that an MS4 permit would include a requirement for an inspection program for common industrial/commercial businesses, such as restaurants and gas stations, within the jurisdiction of the MS4. *Id.* at 76 - 77, 81. The inspection requirements of the LA MS4 permit are consistent with the recommended activities in the Guide.

²The provision applicable to the TMDL permittees is also clearly consistent with EPA's 2002 guidance on TMDLs and storm water permitting. "Establishing Total Maximum Daily Load (TMDL) Wasteload Allocations (WLA's) for Storm Water Sources and NPDES Permit

of BMPs for stormwater management programs, which recommends a number of BMPs to reduce trash discharges. See <http://cfpub.epa.gov/npdes/stormwater/menuofbmps/index.cfm?action=browse&Rbutton=detail&bmp=5>. Among the recommendations is "improved infrastructure" for trash management when necessary, which includes the placement of trash receptacles at appropriate locations based on expected need. The requirements of the Los Angeles County MS4 permit are consistent with this recommendation. See also, "MS4 Program Evaluation Guidance" (January 2007) at pp. 50, 79. EPA's expectations of the programs to reduce pollutants to the maximum extent practicable specifically refer to control of litter and trash, regardless of whether the particular receiving water is already impaired for trash.

I hope that this explanation helps clarify EPA's expectations for MS4 permit requirements under the Clean Water Act. I look forward to continuing to work with the State on our shared goal of ensuring consistency and effectiveness in storm water permitting as a vital tool in protecting the quality of our waters. Should you have further questions about these issues, please have your staff contact Douglas Eberhardt of my staff at (415) 972-3420 or have your counsel's office contact Laurie Kermish of the Office of Regional Counsel at (415) 972-3917.

Sincerely,

Alexis Strauss

**Proposed 2007 MS4 Permit
Track Changes from 2002 MS4 Permit**

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD
SANTA ANA REGION

ORDER NO. R8-2002-00112007-XXXX
NPDES NO. CAS 618033

WASTE DISCHARGE REQUIREMENTS

FOR
THE RIVERSIDE COUNTY FLOOD CONTROL AND WATER CONSERVATION DISTRICT, THE
COUNTY OF RIVERSIDE, AND THE INCORPORATED CITIES OF RIVERSIDE COUNTY
WITHIN THE SANTA ANA REGION
AREAWIDE URBAN RUNOFF

The California Regional Water Quality Control Board, Santa Ana Region (hereinafter the "Regional Board") finds that:

1. On ~~April 27~~^{August 30}, 2007~~0~~, the Riverside County Flood Control and Water Conservation District (hereinafter referred to as "RCFC&WCD" or "Principal Permittee", as context indicates), in cooperation with the County of Riverside, (the "County") and the incorporated cities of Beaumont, Calimesa, Canyon Lake, Corona, Hemet, Lake Elsinore, Moreno Valley, Murrieta, Norco, Perris, Riverside, and San Jacinto (hereinafter with the County, collectively referred to as the "Co-Permittees", and collectively with the Principal Permittee, the "Permittees"), jointly submitted a National Pollutant Discharge Elimination System (NPDES) Application No. CAS 618033, a Report of Waste Discharge (the "ROWD"), to renew the municipal separate storm sewer system ("MS4" and as defined in Appendix 4, Glossary) NPDES permit (the "Order") for the Santa Ana River ~~W~~watershed (the "Region") within Riverside County (the "Order") dealing with urban storm water runoff (hereinafter as defined and qualified in Findings 123 and 143, below, "Urban Runoff") in the "Permit Area" (as defined in Appendix 4, Glossary) that includes the "Urban Area" as shown in Appendix 1 and those portions of "Agriculture" and "Open Space" as shown on Appendix 1 that convert to industrial, commercial or residential use during the term of this Order. To more effectively carry out the requirements of this Order, the Permittees have agreed that the RCFC&WCD will continue as the Principal Permittee and the County and the incorporated cities will continue as the Co-Permittees.
2. On February 16, 1999, the City of Murrieta annexed 1,124 acres, increasing the land area of the City to 18,273 acres. Of the acreage annexed, approximately 375 acres (or 2% of the City's land area) was in the unincorporated area of Riverside County within the Region. The Regional Board's construction database shows that approximately 247 acres out of 375 acres are proposed for development based on Notice of Intent ("NOI") submittals. The City of Murrieta has expressed its intent to be a Co Permittee in this Order and for the purposes of this Order shall be considered as such.
2. On July 13, 1990, the Regional Board adopted the original Riverside County regional MS4 permit, Order No. 90-104 (NPDES No. CA 8000192), for Urban Runoff from areas in Riverside County within the Permit Area. On March 8, 1996, the Regional Board renewed Order No. 90-104 by adopting the second regional MS4 permit, Order No. 96-30, (NPDES No. CAS618033). On October 25, 2002, the Regional Board renewed Order No. 96-30 by adopting the third regional MS4 permit, Order No. R8-2002-0011. ~~expired on March 1, 2001, and on March 2, 2001; Order No. 96 30 was administratively extended in accordance with 40CFR Part 122.6 and Title 23, Division 3, Chapter 9, Section 2235.4 of the California Code of Regulations.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 3 of 4246

3. This Order renews Order No. ~~R8-2002-0011 96-30~~ (NPDES No. CAS618033), and regulates discharges of Urban Runoff from the MS4s within Riverside County ~~under the jurisdiction of and/or maintenance responsibility of the Permittees.~~ This Order is intended to regulate the discharge of "pPollutants" (as defined in Appendix 4, Glossary) in Urban Runoff from anthropogenic (generated from non-agricultural human activities) sources under the jurisdiction of and/or maintenance responsibility control of the Permittees and is not intended to address background or naturally occurring pPollutants or flows.
4. The Permittees submitted a revised Drainage Area Management Plan ("DAMP" and defined in Appendix 4, Glossary) as contained in Appendix B of the ROWD, dated April 27, 2007. This DAMP is a dynamic document that defines MEP for Permittee activities and is incorporated by reference and an enforceable extension of this MS4 Permit. Future Permittee modifications of the DAMP, once approved by the Regional Board Executive Officer, are also enforceable extensions of this MS4 Permit.
5. The federal Clean Water Act (the "CWA") established a national policy designed to help maintain and restore the physical, chemical and "biological integrity" (as defined in Appendix 4, Glossary) of the nation's waters. In 1972, the CWA established the NPDES permit program to regulate the discharge of pPollutants from "point sources" (as defined in Appendix 4, Glossary) to waters of the nation (the "Waters of the U.-S." and as defined in Appendix 4, Glossary). From 1972 to 1987, the main focus of the NPDES program was to regulate conventional pPollutant sources such as sewage treatment plants and industrial facilities. As a result, on a nationwide basis, "non-point sources" (as defined in Appendix 4, Glossary), including agricultural runoff and Urban Runoff, now contribute a larger portion of many kinds of pPollutants than the more thoroughly regulated sewage treatment plants and industrial facilities.
6. Studies conducted by the United States Environmental Protection Agency (the "USEPA"), the states, counties, cities, flood control districts and other political entities dealing with urban "storm water" (as defined in Appendix 4, Glossary) runoff indicate the following major sources of Urban Runoff "pPollution" (as defined in Appendix 4, Glossary) nationwide:
 - a. Industrial sites where appropriate pPollution ~~Prevention~~ control and best management practices ("BMPs" and as defined in Appendix 4, Glossary)¹ are not implemented;
 - b. Construction sites where erosion and siltation controls and BMPs are not implemented; and,
 - c. Runoff from urbanized areas.
7. The 1987 amendments to the CWA added Section 402(p) that required the USEPA to develop permitting regulations for storm water discharges from MS4s and from industrial facilities, including construction sites. The USEPA promulgated the final Phase I storm water regulations on November 16, 1990. Neither the 1987 amendments to the CWA nor the Phase I storm water regulations (40 CFR Part 122) have been amended since their effective dates.

¹ Best Management Practices (BMPs) are water quality management practices that are maximized in efficiency for the control of storm water runoff pollution.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 4 of 4246

8. Section 402 (p) of the CWA establishes two different performance standards for storm water discharges. NPDES MS4 permits require controls to reduce the discharge of pollutants to the Maximum Extent Practicable- (the "MEP") [See discussion of this term in the Glossary, Appendix 4]. ~~NPDES permits issued for industrial storm water discharges (including construction activities) must meet Best Available Technology ("BAT") (as defined in Appendix 4, Glossary) and Best Conventional Pollutant Control Technology ("BCT") (as defined in Appendix 4, Glossary) standards.~~ The CWA and the USEPA regulations promulgated pursuant thereto allow each state the flexibility to decide what constitutes the MEP.

9. Prior to the USEPA's promulgation of the final storm water regulations, three counties (Orange, Riverside, and San Bernardino) and their incorporated cities located within the Regional Board's jurisdiction requested area-wide NPDES MS4 permits. These area-wide MS4 NPDES permits are:
 - a. Orange County, NPDES No. CAS 618030.
 - b. Riverside County, NPDES No. CAS 618033
 - c. San Bernardino County, NPDES No. CAS 618036

10. Consistent with the CWA and the USEPA regulations promulgated pursuant thereto, the State Water Resources Control Board (the "State Board") and the Regional Board have adopted a number of permits to address pollution from the sources identified in Finding 6, above. Industrial activities (as defined in 40 CFR 122.26(b)(14)) and construction sites of one five acres or more are to be covered under one of the following permits and those individuals or entities that engage in such activities are required to secure permission to engage in such identified activities pursuant to the provisions of one of the following permits:
 - a. State Board Order No. 97-03-DWQ, for storm water runoff from industrial activities (NPDES No. CAS000001), (the "General Permit-Industrial Activities Storm Water Permit")
 - b. State Board Order No. 99-08-DWQ, for storm water runoff from construction activities (NPDES No. CAS000002), (the "General Permit-Construction Activity Storm Water Permit"). Order No. 99-08-DWQ was amended by State Board Resolution No. 2001-046 on April 26, 2001, to incorporate monitoring provisions as directed by the Superior Court, County of Sacramento.
 - c. State Board Order No. 99-06-DWQ (NPDES No. CAS000003) for storm water runoff from facilities (including freeways and highways) owned and/or operated by the California Department of Transportation ("Caltrans").
 - d. State Board Order No. 2003-0007-DWQ, for discharges of stormwater runoff associated with small linear underground/overhead construction projects (NPDES No. CAS000005), (the "General Permit-Small Linear Underground Projects).
 - d. ~~Regional Board Order No. 01-34, adopted on January 19, 2001, for storm water discharges associated with new development (construction) to surface waters in the San Jacinto sub-watershed ("San Jacinto Watershed Construction Activities Permit").~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 5 of 4246

- e. The Regional Board also issues individual storm water permits for certain industrial facilities within the Santa Ana River Watershed. Currently there is one industrial storm water NPDES permit that has been issued by the Regional Board for a facility (March Air Reserve Base) located within the Permit Area. Additionally, the Regional Board has issued NPDES permits for a number of facilities that discharge process wastewater and storm water; storm water discharge requirements are included in such a facility's NPDES permit.

~~The San Bernardino County Flood Control District and RCFC&WCD, in cooperation with local affected municipalities, are coordinating an effort to construct flood control facilities in the Chino-Corona Agricultural Preserve area (the "Preserve Area") located on the border of San Bernardino and Riverside Counties. The Preserve Area has the highest concentration of dairy animals in the nation. The ground and surface water quality in the Preserve Area have been adversely impacted by these dairy operations. The dairies within the Permit Area are regulated under the Regional Board's "General Dairy Permit" (Order No. 99-11, NPDES No. CAG018001). The General Dairy Permit allows discharge of storm water from dairies only for storms exceeding a 24 hour, 25-year frequency. The portion of the Preserve Area within San Bernardino County lacks appropriate flood control facilities, and runoff from upstream urbanized areas within San Bernardino County often inundates some of the dairies in the Preserve Area, even during light or moderate storm and runoff events. This causes dairy waste containment facilities to fail and overflow into surface drainage facilities. This overflow causes nutrient, total dissolved solids (TDS), total suspended solids (TSS), and microbial problems in the "receiving waters" (as defined in Appendix 4, Glossary). However, there are only small areas of urbanized development in Riverside County upstream of the dairies subject to flooding. The RCFC&WCD is the lead agency responsible for engineering, design, contract administration, environmental review, and overall project management of the County Line Channel whose construction is intended to address this problem.~~

11. Section 13225 of the California Water Code (the "Water Code") identifies the Regional Board as being the enforcement authority for NPDES permits, including the General Permit-Industrial Activities Storm Water Permit (referenced in Finding 10.a., above), the General Permit and the Construction Activity Storm Water Permits (referenced in Finding 10.b.), and the General Permit-Small Linear Underground Projects (referenced in Finding 10.d., above), which are (collectively referred to as, the "General Storm Water Permits") "Storm Water General Permits." However, in many areas, the industrial and construction sites discharge directly into MS4 facilities owned and operated by the Permittees. These industrial and construction sites are also regulated under local ordinances and regulations. The Co-Permittees review plans for developments in accordance with the "Subdivision Map Act" (Section 66400 et seq. of the California Government Code), the California Environmental Quality Act ("CEQA") (Section 21000 et seq. of the California Public Resources Code), and local general plans and implementing ordinances and regulations to assure that "new developments" (as defined in Appendix 4, Glossary) proceed in an orderly, and safe manner, consistent with each Co-Permittee's general plan. This Order establishes a responsibility of the Permittees to manage Urban Runoff. A coordinated effort between the Permittees and the Regional Board staff is critical to avoid duplicative and overlapping efforts when overseeing the compliance of dischargers covered under the General Storm Water General Permits. As part of this coordination, the Permittees ~~have been notifying~~ Regional Board staff when they observe, during their routine activities, conditions that result in a threat or potential threat to Receiving wWater quality, or when a required industrial facility or construction activity fails to obtain coverage under the appropriate General Storm Water General Permit. To more effectively

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 6 of 4246

coordinate these activities, the Regional Board staff intends to post their inspection activities related to administration of the General Storm Water General Permits on the Regional Board website.

12. Urban Runoff includes those discharges from residential, commercial, industrial, and construction areas within the Permit Area and excludes discharges from feedlots, dairies, farms, and open space (also see Finding 134, below). Urban Runoff discharges consist of Storm Water and "non-storm water" (as defined in Appendix 4, Glossary) surface runoff from drainage sub-areas with various, often mixed, land uses within all of the hydrologic drainage areas that discharge into the Waters of the U.-S. In addition to Urban Runoff, the MS4s regulated by this Order receives flows from agricultural activities, open space, state and federal properties and other non-urban land uses not under the control of the Permittees. The quality of the discharges from the MS4s varies considerably and is affected by, among other things, past and present land use activities, basin hydrology, geography and geology, season, the frequency and duration of storm events, and the presence of past or present Illegal Discharges (as defined in Appendix 4, Glossary) and allowed discharges² and Illicit Connections (as defined in Appendix 4, Glossary)³.
13. The Permittees lack legal jurisdiction over Storm Water and other discharges into their respective MS4 facilities from agricultural activities, California and federal facilities, utilities and special districts, Native American tribal lands, non-Permittee wastewater management agencies and other Point and Non-point Source discharges otherwise permitted by or under the jurisdiction of the Regional Board. The Regional Board recognizes that the Permittees should not be held responsible for such facilities and/or discharges. Similarly, certain activities that generate Pollutants present in Urban Runoff are beyond the ability of the Permittees to eliminate. Examples of these include operation of internal combustion engines, atmospheric deposition, brake pad wear, tire wear, residues from lawful application of pesticides, nutrient runoff from agricultural activities, bacteria from wildlife (including birds and feral dogs and cats) and leaching of naturally occurring minerals from local geography.
14. Urban Runoff may contain elevated levels of pathogens (bacteria, protozoa, viruses), "sediment" (as defined in Appendix 4, Glossary), trash, fertilizers (nutrients, compounds of nitrogen and phosphorus), pesticides (DDT, Chlordane, Diazinon, Chlorpyrifos), heavy metals (cadmium, chromium, copper, lead, zinc), and petroleum products (oil, grease, petroleum hydrocarbons, polycyclic aromatic hydrocarbons). Urban Runoff can carry these Pollutants to rivers, streams, and lakes within the Permit Area (collectively the "Receiving Waters"). In addition, although infrequently, Urban Runoff from the Permit Area can carry these Pollutants to other receiving waters such as the Pacific Ocean. These Pollutants can then impact the "Beneficial Uses" (as defined in Appendix 4, Glossary) of the Receiving Waters and can cause or threaten to cause a condition of Pollution or "Nuisance" (as defined in Appendix 4).

² Illegal discharge means any disposal, either intentionally or unintentionally, of material or waste to land or MS4s that can pollute storm water or create a nuisance. The term illegal discharge includes any discharge to the MS4 that is not composed entirely of storm water, except discharges pursuant to an NPDES permit, discharges that are identified in Section II. C. of this Order, and discharges authorized by the Executive Officer.

³ Illicit Connection means any connection to the MS4 storm drain system that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illicit connection includes all non storm-water discharges and connections except discharges pursuant to an NPDES permit, discharges that are identified in Section II, Discharge Limitations/Prohibitions, of this Order, and discharges authorized by the Executive Officer.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 7 of 4246

15. Pathogens (from sanitary sewer overflows, septic system leaks, and spills and leaks from portable toilets, pets, wildlife, and human activities) can impact water contact recreation and non-contact water recreation. "Floatables" (from trash) are an aesthetic nuisance and can be a substrate for algae and insect vectors. Oil and grease can coat birds and aquatic organisms, adversely affecting respiration and/or thermoregulation. Other petroleum hydrocarbon components may cause "toxicity" (as defined in Appendix 4, Glossary) to aquatic organisms and may impact human health. Suspended and settleable solids (from sediment, trash, and industrial activities) may be deleterious to benthic organisms and may cause anaerobic conditions to form. Sediments and other suspended particulates may cause turbidity, clog fish gills and interfere with respiration in aquatic fauna. They may also screen out light, hindering photosynthesis and normal aquatic plant growth and development. However, it is recognized that storm flows from non-urbanized areas such as "National Forest," "State Park," "Wilderness," and "Agriculture", as shown on Appendix 1, naturally exhibit high levels of suspended solids due to climate, hydrology, geology and geography.⁴ Toxic substances (from pesticides, petroleum products, metals, and industrial "wastes" (as defined in Appendix 4, Glossary)) can cause acute and/or chronic toxicity, and can bioaccumulate in organisms to levels that may be harmful to human health. Nutrients (from fertilizer use, fire fighting chemicals, decaying plants, confined animal facilities, pets, and wildlife) may cause excessive algal blooms. These blooms may lead to problems with taste, odor, color and increased turbidity, and may depress the dissolved oxygen content, leading to fish kills.
16. The water quality assessment conducted by Regional Board staff has identified a number of beneficial use impairments due, in part, to agricultural and Urban Runoff. Section 303(b) of the CWA requires the USEPA and each state that has been delegated NPDES permitting authority each of California's Regional Water Quality Control Boards to routinely monitor and assess the quality of waters of their respective regions. If this assessment indicates that beneficial uses are not met, then that waterbody must be listed under Section 303(d) of the CWA as an impaired waterbody ("Impaired Waterbody") (as defined in Appendix 4, Glossary). The 2006-1998 water quality assessment listed a number of water bodies within the Permit Area as impaired pursuant to Section 303(d). In the Permit Area, these include: Canyon Lake (for nutrients and pathogens); Lake Elsinore (for nutrients, organic enrichment/low D.O., PCBs and unknown toxicity and sedimentation); Lake Fulmor (for pathogens); Santa Ana River, Reach 3 (for nutrients, pathogens, salinity, TDS, and chlorides); and Santa Ana River, Reach 4 (for pathogens). However, the Regional Board now recognizes that Reach 3 of the Santa Ana River is meeting the standards for nutrients, salinity, TDS and chlorides and has requested that this Reach be de-listed for these constituents in the 2002 CWA 303(d) list.
17. Federal regulations require that a total maximum daily load ("TMDL" as defined in Appendix 4, Glossary) be established for each 303(d) listed waterbody for each of the pollutants causing impairment. The TMDL is the total amount of the problem pollutant that can be discharged and still attain "Water Quality Standards" (as defined in Appendix 4, Glossary) in the receiving water, i.e., Receiving Water Quality Objectives (as defined in Appendix 4, Glossary) are met and the beneficial uses are protected. The TMDL is the sum of the

⁴ Riverside County Flood Control and Water Conservation District's "Hydrology Manual," dated April 1978 and page II-4 of "Santa Ana River, Design Memorandum No. 1, Phase II GDM on the Santa Ana River Mainstem, including Santiago Creek, Volume 2, Prado Dam." dated August 1988 and D.I. Inman & S.A. Jenkins "Climate Change and the Episodicity of Sediment Flux in Small California Rivers," Journal of Geology, Volume 107, pp. 251-270, 1999.

individual Waste Load Allocations (“WLA”) as defined in Appendix 4, Glossary) for pPoint sSource inputs, Load Allocations (“LA”) as defined in Appendix 4, Glossary) for nNon-point sSource inputs and natural background, with a margin of safety. The TMDLs are one of the bases for limitations established in waste discharge requirements (“Waste Discharge Requirements” and defined in Appendix 4, Glossary). TMDLs are being developed for sediment, pathogens, and nutrients for Lake Elsinore and Canyon Lake.

18. The 2006 CWA 303(d) List of Water Quality Limited Segments identifies the following waterbodies in the Region as potentially impaired waterbodies:

<u>Waterbody</u>	<u>Pollutant</u>	<u>Potential Sources</u>	<u>Proposed TMDL Completion</u>
<u>Canyon Lake</u>	<u>Pathogens</u>	<u>Non-point Source</u>	<u>2006 (pending)</u>
<u>Lake Elsinore</u>	<u>PCBs</u> <u>Unknown Toxicity</u>	<u>Unknown</u> <u>Unknown Non-point Source</u>	<u>2019</u> <u>2007</u>
<u>Lake Fulmor</u>	<u>Pathogens</u>	<u>Unknown Non-point Source</u>	<u>2019</u>
<u>Santa Ana River, Reach 4</u>	<u>Pathogens</u>	<u>Non-point Source</u>	<u>2019</u>

19. TMDLs for Canyon Lake and Lake Elsinore (Board Order R8-2004-0037) and the Middle Santa Ana River (Board Order R8-2005-0001) have been adopted by the Regional Board and approved by USEPA per the requirements of the CWA. These TMDLs include Urban WLAs that are now incorporated in Chapter 5 of the Water Quality Control Plan (the “Basin Plan” and as defined in Appendix 4, Glossary). The appropriate Permittees shall comply with the Urban WLA described in Chapter 5 of the Basin Plan. Those Urban WLAs are incorporated into this Order by reference.

20. USEPA’s Interim Permitting Approach for Water Quality Based Effluent Limitations in Storm Water Permits, 60 FR 43761 (Aug 26, 1996) recognizes the need for an iterative approach to control Pollutants in storm water discharges. In addition, the TMDLs described in Finding 19 were based on preliminary and incomplete data and were intended to be revised upon collection and analysis of a more comprehensive data set. Therefore, the variability in the system and the minimal data generally available make it difficult to determine with precision or certainty actual and projected loadings for individual dischargers or groups of dischargers. It is therefore the intention of the Regional Board that these TMDL WLA be implemented through a phased and iterative BMP process. To assist with this process, the Regional Board staff developed TMDL Implementation Plans for each TMDL. In summary, the Implementation Plans assign responsibilities to specific MS4 dischargers to identify sources of impairment, to propose BMPs to address those sources, and to monitor, evaluate and revise BMPs based on the effectiveness of the BMP implementation program. Specific Implementation Plan tasks are described in Chapter 5 of the Basin Plan and are assigned to one or more of the Permittees. Requirements of the TMDL Implementation Plan tasks are incorporated into this MS4 Permit and the DAMP. Additional details regarding specific Implementation Plan task requirements are available in Chapter 5 of the Basin Plan. Several of these Implementation Plan tasks are

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 9 of 4246

also jointly assigned to non-Permittee stakeholders. The Permittees have established TMDL Task Forces to jointly implement and coordinate those Implementation Plan tasks.

21. It is the Regional Board's intention that this iterative and phased BMP evaluation process be conducted simultaneously with the Permit renewal process. To that end, the Permittees have proposed BMP programs consistent with the aforementioned TMDL Implementation Plan tasks as part of Section 13 of the DAMP submitted with the ROWD. The Regional Board finds these programs to be consistent with the requirements of the TMDL and their respective Implementation Plans. These BMP programs shall be implemented and monitored during the course of the Permit. As part of the Permittees next ROWD, the Permittees shall evaluate the effectiveness of the BMP programs and propose BMP program modifications as necessary to achieve compliance with the TMDL WLA by the dates specified in Chapter 5 of the Basin Plan.
22. The Permittees are providing assistance and cooperating with Regional Board staff in the TMDL efforts. The Permittees shall revise their Drainage Area Management Plan ("DAMP," and defined in Appendix 4, Glossary), at the direction of the Regional Board Executive Officer (the "Executive Officer"), to incorporate program implementation amendments so as to comply with Regional, "watershed" (as defined in Appendix 4, Glossary) specific requirements, and/or WLAs developed and approved pursuant to the process for the designation and implementation of any newly approved TMDLs for Impaired Waterbodies adopted during the course of the MS4 Permit.
23. The area shown on Appendix 1 Region contains 1,396,293 square miles (or 19.147.7% of the 7,300 square miles within Riverside County) and includes 12 of the 24 municipalities within Riverside County. The California Department of Finance estimates that as of January 1, 2006, the population of Riverside County is 1,953,330,644,344 of which 864,542,759,877 persons reside within the 142 municipalities and an additional 368,437,338,630 persons reside in the unincorporated area that is within the area shown on Appendix 1 of the Region (or a total of 1,232,979,098,507 persons or 63.166.8% of Riverside County's population). ThreeFive of the municipalities (Beaumont, Calimesa, and Canyon Lake, Norco, and San Jacinto) have populations of 25,000 or less; five three municipalities (Hemet, Lake Elsinore, Norco, and Perris and San Jacinto) have populations between 25,001 and 70,000; Corona has a population of 144,661,433,966, Moreno Valley's population is 174,565,146,435 and Riverside has 287,820,269,402 residents. [Population figures for the eCity of Murrieta have been omitted because only 375 acres (2%) of the City's Land land Area area is within the Permit aArea, shown on Appendix 1. (See Finding No. 2.)] Of the total territory within the area shown on Appendix 1 Region, approximately 190,346.7 square miles are within the 124 incorporated areas and 1,206,944.6 square miles are unincorporated. General land uses within the 1,396,293.3 square miles comprising the area shown on Appendix 1 Region are identified in Appendix 1, based on Riverside County Assessor's Roll for February 2006 Fiscal Year 2004-2002, as follows: 46,109.3 square miles are used or zoned for commercial/industrial purposes (3.38.5%), 110,164,98.7 square miles for residential purposes (7.945.4%), 15.3 square miles for parks and recreational facilities (1.1%), 18,437,0.4 square miles are utilized for streets and roads improved roadways (including roadways owned by Caltrans) (1.35.4%), 709,347,53.9 square miles are vacant or utilized for preserves or open space (50.858.3%), 109.58 square miles are used for rural residential (7.9%) and 75,984,61.3 square miles are used for agricultural purposes (5.412.5%). There are 311.04 square miles of federal, state, tribal and non-County jurisdictional lands government owns 310.7 square miles (24%) of the territory within the area shown on Appendix 1 Region.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 10 of 4246

24. Some portions of Riverside County within the Permit Area have been developed or zoned for residential, commercial and industrial uses. Urban development generally increases the area of impervious surfaces and ~~sStorm wWater runoff~~ volume and velocity; and decreases the area of previously vegetated surfaces available for infiltration of ~~sStorm wWater~~, depending on soils, topography, climate, precipitation volume and patterns, and other factors. However, Bbased on the procedures in Section D of the RCFC&WCD Hydrology Manual of RCFC&WCD, dated April 1978, it is feasible that, in semi-arid regions such as this Permit Area, development may result in the creation of a net increase in absorption. —Increases in runoff volume and velocity may cause scour, erosion (sheet, rill and/or gully), aggradation (raising of a streambed from ~~sSediment~~ deposition), changes in fluvial geomorphology, hydrology, and changes in aquatic ecosystem (collectively, “Conditions of Concern” and as defined in Appendix 4, Glossary). The Permittees are the owners and operators of the MS4s and have authority (except as qualified in Finding 134, above) to control most of the discharges of Urban Runoff to the MS4s systems. The Permittees have established appropriate legal authority to address their respective MS4 facilities’ exposure to ~~pPollutant~~ loads from discharges of Urban Runoff and have enhanced the design requirements for MS4 facilities to address ~~these~~ potential discharges from aNew dDevelopment and Significant Redevelopment. Co-Permittees have adopted grading and/or erosion control ordinances, guidelines and BMPs for municipal, commercial, and industrial activities, and, along with RCFC&WCD, have approved and are begun ~~implementing~~ implementation of the DAMP. The Permittees ~~have implemented most of the programs and policies that they developed~~. They must continue to implement an effective combination of these programs, policies, and legal authority, modify and enhance such programs and policies, and other additional requirements as identified herein, to ensure that ~~pPollutant~~ loads resulting from Urban Runoff are properly controlled and managed to the MEP.”
25. The Permittees own and/or operate the MS4s through which Urban Runoff is discharged into the Waters of the U.-S. The Permittees have identified major outfalls (with a pipe diameter of 36 inches or greater or drainage areas draining 50 acres or more) and have submitted maps of existing MS4 facilities. The Co-Permittees reported having approximately 153.3 miles of underground storm drains, and 21.3 miles of channels. The RCFC&WCD reported having 135 miles in underground storm drains and 133 miles of channels.
26. The MS4s generally ~~convey~~ convey ~~stain~~ stain ~~aNon-sStorm wWater~~ flows that may include runoff from agriculture and landscape irrigation, residential car washing, ~~miscellaneous washing and cleaning operations~~, and other ~~miscellaneous nuisance~~ flows. In addition, these facilities are used to convey water produced from the Arlington Desalter and deliveries of other water for water conservation. During normal dry weather conditions, very little Urban Runoff reaches Receiving Waters⁵. Non-storm ~~wWater~~ discharges into the MS4s and to the Waters of the U. S. containing ~~pPollutants~~ are prohibited, unless they are regulated under a separate NPDES permit; certain types of ~~aNon-storm wWater~~ containing insignificant amount of ~~pPollutants~~ are exempt as indicated in Discharge Limitations/Prohibitions, Section II.-C. of this Order.
27. Order Nos. 90-104, ~~and Order No. 96-30 and 02-11~~ required the Permittees to: (1) develop and implement the DAMP and Urban Runoff and Receiving Water monitoring and reporting

⁵ Based upon a field investigation report of the Storm Drain Outlets into the Santa Ana River conducted by the RCFC&WCD and dated May 28, 2002.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 11 of 4246

programs; (2) eliminate illegal discharges and illicit connections ("IC/IDs") to the MS4s; and (3) enact the necessary legal authority to effectively prohibit such IC/IDs illegal discharges and illicit connections. The overall goal of these requirements was to reduce pollutant loading to surface waters from Urban Runoff to the MEP. The DAMP outlines the major programs and policies for controlling pollutants in Urban Runoff and the DAMP was approved by the Executive Officer on January 18, 1994. Since then, the Urban Runoff monitoring program has been expanded and the DAMP continues to be a dynamic document. This Order requires the Permittees to continue to implement the BMPs listed in the DAMP, and update or modify the DAMP, when appropriate, consistent with the MEP and other applicable standards; and to continue to effectively prohibit IC/IDs illegal discharges and illicit connections to their respective MS4s.

28. A revised Water Quality Control Plan (the "Basin Plan") was adopted by the Regional Board and became effective on January 24, 1995. The Basin Plan defines the numeric and narrative Water Quality Objectives and Beneficial Uses of the Receiving Waters in the Region. These Beneficial Uses include municipal and domestic supply, agricultural supply, industrial service supply, groundwater recharge, hydropower generation, water contact recreation, non-contact water recreation and sportfishing, warm freshwater habitat, cold freshwater habitat, preservation of biological habitats of special significance, wildlife habitat and preservation of rare, threatened, or endangered species. The Basin Plan also incorporates by reference all State Board water quality control plans and policies.
29. The ultimate goal of this Order MS4 permit is to protect these Beneficial Uses of the Receiving Waters by ensuring that the flows from the MS4s does not cause or contribute to an exceedance of "Water Quality Objectives" (as defined in Appendix 4, Glossary) for the Receiving Waters. The DAMP identifies programs and policies, including BMPs, to achieve this goal. These BMPs are organized into two components: BMPs for existing facilities and BMPs for New Development. Both components include regulatory activities, public education programs, solid waste management, and operations and maintenance activities.
30. There are pollutants in Urban Runoff from privately owned and operated facilities such as residences, businesses and commercial establishments and public and private institutions. A successful NPDES MS4 permit program should include the participation and cooperation of public entities, private businesses, and public and private institutions. Therefore, public education is a critical element of the DAMP. As the population increases in the Permit Area, it will be even more important to continue to educate the public regarding the impact of human activities on the quality of Urban Runoff.
31. The Co-Permittees have developed conditions of approval for projects requiring coverage under the General Permit-Construction Activity Permits for maps or permits requiring discretionary approval that are to be satisfied prior to issuing a grading or building permit for construction sites of one five acres or more. After March 10, 2003, these conditions of approval will be extended to construction sites on one (1) acre or more, consistent with the acreage criteria of the current Construction Activity Permits.
32. This Order requires the Permittees to continue to implement the BMPs listed in the approved DAMP and to continue to effectively prohibit IC/IDs illegal discharges and illicit connections to their respective MS4s. One of the major elements of the DAMP is a Storm Water/Urban Runoff Management and Discharge Control Ordinance, and Each of the Co-Permittees has

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 12 of 4246

adopted such an ordinance and ordinances addressing grading and erosion control (collectively, the "Storm Water Ordinance" and as defined in Appendix 4, Glossary). The purpose of each Storm Water Ordinance is to prohibit ~~p~~Pollutant discharges via IC/IDs to ~~in~~ the Permittees respective MS4s and to regulate illicit connections and non-storm water discharges to said MS4s.

33. The California Constitution and Government Code create in the Co-Permittees planning police powers that mandate that the Co-Permittees review and condition ~~a~~New ~~d~~Development consistent with the Subdivision Map Act, CEQA, and their respective general plans, ordinances, and resolutions to ensure the general public's health and safety. If these constitutional and statutory mandates are not properly implemented and local ordinances and resolutions are not properly enforced, there is a creditable potential that ~~a~~New ~~d~~Development could result in the discharge of ~~p~~Pollutants via Urban Runoff to the Receiving Waters ~~within~~ the Permit Area from Urban Runoff.
34. This Order requires the Permittees to examine the source of ~~p~~Pollutants in Urban Runoff from those activities that the Permittees conduct, approve, regulate and/or for which they issue a license or permit. This Order also requires the implementation of control measures to protect ~~b~~Beneficial ~~u~~Uses and attain "Receiving Water Quality Objectives", as defined in the Basin Plan.
35. Each Co-Permittee conducts inspections of those construction sites for which it has issued either a grading or building permit to determine compliance with its ordinances, regulations, and codes, including its Storm Water Ordinance. Each Co-Permittee, consistent with its ordinances, rules and regulations, inspect each site for which a grading or building permit has been issued for compliance with the conditions of approval governing the permit. These inspections have been expanded by ~~several of the~~ Co-Permittees to ~~survey and address~~ issues related to prevention of Urban Runoff and to determine that a site has secured coverage under the General ~~Permit-Construction-Activity Storm Water Permit~~. Once a certificate of occupancy has been issued, the Co-Permittees have limited jurisdiction to inspect ~~non-commercial/industrial~~ the sites on an ongoing basis.
36. The ~~DAMP~~Permittees have established the "Enforcement/Compliance Strategy," dated December 20, 2001 (the "E/CS") that addresses compliance strategies with regard to industrial, and commercial facilities and construction sites. In addition, as part of their Urban Runoff management activities, the Principal Permittee and the County entered into an agreement, dated August 10, 1999 by which they have developed and funded, in cooperation with the Riverside County Environmental Health Department, the "Compliance Assistance Program" (the "CAP") which includes a storm water survey component as part of existing inspections of "hazardous material" (as defined in Appendix 4, Glossary) handlers and retail food service activities. The initial phase of the CAP consisted primarily of educational outreach to the inspected facilities. The CAP has entered a second phase, which involves ~~and~~ a detailed storm water compliance surveys for each facility that must secure a "hazardous materials" (as defined in Appendix 4, Glossary) permit for either storing, handling or generating such materials (there are approximately 5,500 facilities of which approximately 2,300 are inspected annually, and all facilities are inspected at least once during a two year cycle) and retail food facilities (there are approximately 6,750 facilities, all of which are inspected 1 to 3 times annually). The type of industrial/commercial establishment that is inspected includes, but is not limited to, automobile mechanical repair, maintenance, fueling, or cleaning operation,

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 13 of 4246

automobile or other vehicle body repair or painting operations, and painting or coating operations. ~~Any e~~Completed surveys that indicate non-compliance are forwarded to the appropriate jurisdiction's ~~code~~ enforcement division for follow up action. In addition, the cities of Corona and Riverside, which operate publicly owned treatment works ("POTW"), in combination conduct annually on average, approximately 4,400 wastewater pre-treatment inspections, on a variety of industrial and commercial establishments within their respective jurisdictions, including, but not limited to, retail food establishments, car washes, and carpet, drape & furniture cleaning establishments. The Permittees ~~have agreed to~~ notify Regional Board staff when conditions are observed during such inspections that appear to be in violation of either the ~~General~~ Storm Water General Permits or a permit issued by the Regional Board.

37. The Permittees own/operate facilities where industrial or related activities take place that may have an impact on Urban Runoff quality. Some of the Permittees ~~also enter into~~ contracts with outside parties to carry out activities that may also have an impact on Urban Runoff quality. These facilities and related activities include, but are not limited to, street sweeping, catch basin cleaning, maintenance yards, vehicle and equipment maintenance areas, waste transfer stations, corporation and storage yards, parks and recreational facilities, landscape and swimming pool maintenance activities, MS4 maintenance activities and the application of herbicides, algaecides and pesticides. As part of Order 96-30, the Permittees were required to ~~assess public agency activities and facilities for potential impact to Urban Runoff quality and develop their agency specific "Municipal Facility Strategy"~~. This Order requires the Permittees ~~to continued~~ to implementation of BMPs that are ~~reducing~~ reducing pollutant discharges from those Permittee activities/facilities that are found to be significant sources of pollutants in Urban Runoff. This Order prohibits ~~a~~ Non-storm water discharges from facilities owned or operated on behalf of the Permittees unless the discharges are exempt under the Discharge Limitations/Prohibitions Section II.-C. of this Order or are permitted by the Regional Board under an individual NPDES permit.

38. An effective monitoring program characterizes Urban Runoff discharges, identifies problem areas, and determines the impact of Urban Runoff on Receiving Waters and the effectiveness of BMPs. The Principal Permittee administers the Consolidated Program for Water Quality Monitoring⁶ (the "CMP") for the Permittees. The CMP includes wet and dry weather monitoring of MS4 outfalls and Receiving Waters throughout Riverside County. The DAMP (at page 2-4, 1993) ~~indicates that lead, copper, manganese, zinc, BOD, hardness, and nitrates for some of the dry weather samples analyzed exceeded the water quality objectives in samples collected prior to the DAMP. These and other water quality indicators are tabulated on page 2-6 of the DAMP.~~

39. The Permittee's 2006~~0~~ Annual Report (the "Annual Report" and as defined in Appendix 4, Glossary) Pursuant to each NPDES MS4 permit issued by the Regional Board to the Permittees, there is a requirement that an annual report (the "Annual Report") be filed with the Regional Board ~~on or before each November 30th~~ summarized wet weather monitoring data collected between July 1990 and July 2006~~0~~. This summary shows that the average concentration values for a wide array of pollutants do not exceed the Receiving Water Quality Objectives. However, for numerous constituents, the summary contains several maximum

⁶ Consolidated Program for Water Quality Monitoring, Riverside County Flood Control and Water Conservation District, March 1994.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 14 of 4246

~~recorded concentrations that exceed these Receiving Water Quality Objectives. The 2005-2006 Annual Report indicates that Fecal Coliform and pH are regularly measured in excess of applicable Water Quality Objectives. Nutrients including total phosphorus and total nitrogen have also been measured at monitoring stations in the San Jacinto watershed in excess of numeric targets established for the Canyon Lake and Lake Elsinore TMDL. Other detected parameters that have been identified in Annual Reports include heavy metals, nutrients, petroleum products, sediment, and litter. The summary also includes data from the period prior to implementation of the DAMP approved by the Executive Officer in January 1994.~~

40. In general, due to the complexity of hydrologic systems, the data as presented in the 2000 2005-2006 Annual Report are inconclusive in regard to identification of the pPollutant trends and compliance or non-compliance with "Receiving Water Limitations" (as defined in Appendix 4, Glossary)⁷ in various drainage areas represented by the monitoring stations. Consequently, ~~¶~~This Order requires the Permittees, in consultation with Regional Board staff, to re-evaluate ~~prior~~ continue analyzing monitoring data to identify the areas with elevated pPollutant concentrations to focus their source reduction efforts. Also, this Order requires the Permittees to revise the CMP to provide more effective data to support Urban Runoff management. The Permittees will continue their current monitoring efforts on those priority areas pending development and approval of the revised CMP.
41. This Order requires the Permittees to make all necessary revisions to an agreement entitled "NPDES Stormwater Discharge Permit – Implementation Agreement" ~~dated November 12, 1996~~ (the "Implementation Agreement" and as defined in Appendix 4, Glossary). The Implementation Agreement establishes the responsibilities of each Permittee party and a funding procedure for the shared costs.
38. ~~By January 1, 2003, the State Board is required by Water Code Section 13383.5 (Stats. 2001, c. 492 (S.B. 72)) to develop a statewide municipal storm water (Urban Runoff) monitoring and reporting program. Once this statewide program has been developed, the Permittees will be required to develop a revised monitoring and reporting program as specified in this Order and consistent with new requirements developed by the State Board.~~
42. In addition to the Regional Board, a number of other stakeholders are involved in the management of the water resources of the Region. These include, but are not limited to, the incorporated cities in the Region, POTWs, the three counties, and the Santa Ana Watershed Project Authority and its member agencies. The entities listed in Appendix 2 are considered as potential dischargers of Urban Runoff in the Permit Area. It is expected that these entities will also work cooperatively with the Permittees to manage Urban Runoff. The Regional Board, pursuant to 40 CFR 122.26(a), has the discretion and authority to require non-cooperating entities to participate in this Order or to issue individual storm water permits.
43. Cooperation and coordination among the stakeholders (regulators, Permittees, the public, and other entities) are critical to optimize the use of finite/limited public resources and ensure economical management of the water quality in the Region watershed. Recognizing this fact, this Order focuses on watershed management and seeks to integrate the programs of the stakeholders, especially the holders of the three MS4 permits within the Region.

⁷ Receiving Water Limitations are requirements included in this Order issued by the Board to assure that the regulated discharge does not violate ~~w~~Water ~~q~~Quality ~~s~~Standards established in the Basin Plan at the point of discharge to ~~w~~Waters of the State.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 15 of 4246

44. The Regional Board recognizes that a watershed management program should integrate related programs, including the Urban Runoff program and TMDL processes.
45. ~~Illegal discharges to the MS4s can contribute to "contamination" (as defined in Appendix 4, Glossary) of Urban Runoff and other surface waters. The RCFC&WCD was required by Order No. 90-104 to conduct an inspection of underground storm drains and only one illicit connection could be identified. Open channels and other aboveground elements of the MS4 facilities are inspected for evidence of illegal discharges as an element of routine maintenance by the Permittees. The Permittees also developed a program to prohibit IC/IDs illegal discharges and illicit connections to their MS4 facilities. Continued surveillance and enforcement of these programs are required to eliminate IC/IDs illicit connections and illegal discharges. The Permittees have a number of procedures in place to eliminate illicit connections and illegal discharges to the MS4s, including construction, commercial, and industrial facility inspections, MS4 drainage facility inspections, water quality monitoring and reporting programs, and public education.~~
46. The Permittees have the authority to control pollutants in Urban Runoff discharges, to prohibit ~~IC/IDs illicit connections and illegal discharges~~, to control spills, and to require compliance and carry out inspections of the MS4 facilities within their respective jurisdictions. The Co-Permittees have been extended necessary legal authority through California statutes and local charters. Consistent with this statutory authority, each of the Co-Permittees have adopted their respective Storm Water Ordinances. ~~The Co-Permittees are required by this Order to review their respective Storm Water Ordinances and other ordinances, regulations, and codes adopted by them to determine whether the language of said ordinances, regulations, and codes needs to be modified or expanded to allow for enforcement actions, including civil and/or criminal penalties, to be brought by each Co-Permittee consistent with the provisions of this Order.~~
47. "Pollution prevention" (as defined in Appendix 4, Glossary) techniques implemented to the MEP, appropriate planning review procedures, early identification of potential Urban Runoff impacts and mitigation measures may reduce pollution associated with Urban Runoff. The Co-Permittees consider these impacts and appropriate mitigation measures in their respective, land use approval processes and CEQA review processes for development projects to insure consistency with their respective general plans. ~~This Order requires the Co-Permittees to review their respective CEQA review processes, general plans, zoning ordinances, and related regulations and codes to determine the need for any revisions.~~
48. The legislative history and the preamble to the federal storm water regulations indicate that Congress and the USEPA were aware of the difficulties in regulating Urban Runoff solely through traditional end-of-pipe treatment. However, it is the Regional Board's intent that this Order requires the implementation of BMPs to reduce, to the MEP, the discharge of pollutants in Urban Runoff from the MS4s in order to support attainment of Water Quality Standards. This Order, therefore, includes Receiving Water Limitations based upon Water Quality Objectives, prohibiting the creation of nuisances and requiring the reduction of water quality impairment in the Receiving Waters. In accordance with Section 402 (p) of the CWA, this Order requires the Permittees to implement control measures that will reduce pollutants in Urban Runoff discharges to the MEP. The Receiving Water Limitations similarly require the implementation of control measures to protect beneficial uses and attain Water Quality Objectives of the Receiving Waters.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 16 of 4246

49. The Regional Board finds that the unique aspects of the regulation of Urban Runoff discharges through the MS4s, including, but not limited to, the intermittent nature of discharges, difficulties in monitoring and limited physical control over the discharge, will require adequate time to implement and evaluate the effectiveness of BMPs. Therefore, this Order includes a procedure for determining whether Urban Runoff discharges are causing or contributing to exceedances of Receiving Water Limitations and for evaluating whether the DAMP must be revised in order to comply with this aspect of this Order. This Order establishes an iterative process to achieve compliance with the Receiving Water Limitations.

50. Less than one fifth (1/5) of the entire acreage within Riverside County drains into water bodies within the Permit Area. Sixty-three percent of Riverside County's population resides within the Permit Area. The San Diego and the Colorado River Basin Regional Water Quality Control Boards regulate Urban Runoff from those portions of Riverside County outside of the Permit Area.

51. The Santa Ana River watershed is one of the major watersheds within Southern California. This watershed is divided into three sub-watersheds: the "Lower Santa Ana," the "Upper Santa Ana", and the "San Jacinto". The Lower Santa Ana sub-watershed (downstream from Prado Basin) includes the north half of Orange County and the Upper Santa Ana sub-watershed includes the southwestern corner of San Bernardino County and the northwestern corner of Riverside County. The San Jacinto sub-watershed includes the northwest corner of Riverside County south of the Upper Santa Ana sub-watershed.

52. The Santa Ana River is the major Receiving Water in the Permit Area. During non-storm periods the flow in the River is dominated by effluent from POTWs. POTW discharges are regulated under NPDES permits issued by the Regional Board. In addition, the quality of the Santa Ana River within the Upper Santa Ana sub-watershed is greatly influenced by agricultural activities. Urban Runoff from the Permit Area constitutes a minor component of the dry weather flow in the Upper Santa Ana and San Jacinto sub-watersheds of the Santa Ana River.

53. Generally, the portion of the Upper Santa Ana sub-watershed located within San Bernardino County drains to the portion of the Upper Santa Ana sub-watershed within Riverside County and the portion of the Upper Santa Ana sub-watershed located within Riverside County and the San Jacinto sub-watershed drain to Orange County through the Prado Basin and Dam. Prado Dam detains the flows of the Upper Santa Ana and San Jacinto sub-watersheds, specifically Reaches 3 and 4 of the Santa Ana River, and supports an extensive man-made wetlands system, that provides treatment of the detained water. Most of the flow in the Santa Ana River is released from Prado Dam and recharged into the ground-water basin in Orange County. However, as a result of infrequent heavy storm events, flows leaving Prado Dam may continue to coastal waters of the Pacific Ocean.

54. Water from rainfall, snow melt runoff, and surfacing ground water from various areas within the Permit Area either discharge directly to the Santa Ana River or to watercourses tributary to the Santa Ana River. Other major rivers within the Permit Area include the San Jacinto River and Temescal Creek. The San Jacinto Mountain areas drain into the San Jacinto River, which discharges into Canyon Lake and rarely hence into Lake Elsinore. Any overflow from Lake Elsinore is tributary to Temescal Creek, which flows into the Santa Ana River at the Prado Basin. Overflow from Lake Elsinore occurs infrequently, only once every 12 to 15 years.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 17 of 4246

55. The requirements contained in this Order are necessary to implement the Basin Plan. This Order does not contain "numeric effluent limitations" (as defined in Appendix 4, Glossary) for any constituent because the impact of the Urban Runoff discharges on the water quality of the Receiving Waters has not yet been fully determined and because the State Board and the USEPA have determined that numeric effluent limits are not required in the MS4 permits. Continuation of water quality/biota monitoring and analysis of the data are essential to make that determination. In June 2006, the Storm Water Panel recommended to the State that "It is not feasible at this time to set enforceable numeric effluent criteria for municipal BMPs and in particular urban discharges."⁸ The Basin Plan or amendments thereto, may be grounds for the Permittees to revise the DAMP.
56. The Permittees will be required to comply with future ~~w~~Water ~~e~~Quality ~~s~~Standards or discharge requirements, which may be imposed by the USEPA or State of California prior to the expiration of this Order. This Order may be reopened to include ~~W~~LAs or ~~L~~As to address ~~p~~Pollutants in Urban Runoff causing or contributing to the impairments in Receiving Waters and/or other requirements developed and adopted by the Regional Board.
57. The Permittees may petition the Regional Board to issue a separate NPDES permit to any discharger of ~~n~~Non-storm ~~w~~Water into MS4 facilities that they own or operate.
58. The Permittees have implemented programs to control litter, trash, and other anthropogenic materials in Urban Runoff. ~~In addition to the municipal ordinances prohibiting litter, the Permittees should continue to participate in or organize a number of other programs such as solid waste collection programs, household hazardous waste collections, hazardous material spill response, catch basin cleaning, additional street sweeping, and recycling programs to reduce litter and illegal d~~Discharges. These programs ~~should effectively address urban sources of these materials. This Order includes requirements for continued implementation of these programs for litter, trash, and anthropogenic debris control.~~
59. The Regional Board recognizes the importance of watershed management initiatives and regional planning and coordination in the development and implementation of programs and policies related to Receiving Water quality protection. A number of such efforts are underway in which the Permittees are active participants. This Order encourages continued participation in such programs and policies. The Regional Board also recognizes that in certain cases, diversion of funds targeted for certain monitoring and reporting programs to regional monitoring programs may be necessary. The Executive Officer is authorized to approve, after proper public notification and consideration of comments received, the watershed management initiatives and regional planning and coordination programs and regional monitoring programs. The Permittees are required to submit all documents, where appropriate, in an electronic format acceptable to the Executive Officer. These documents will be posted at the Regional Board's website and interested parties will be notified. In addition, the website will include the administrative and civil procedures to appeal any decision made by the Executive Officer.

⁸ "State Water Panel Recommendations to the California State Water Resources Control Board - The Feasibility of Numeric Effluent Limits Applicable to Discharges of Storm Water Associated with Municipal, Industrial and Construction Activities." June 19, 2006, p. 8.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 18 of 4246

60. The federal storm water regulations require public participation in the development and implementation of the Urban Runoff management program. As such, the Permittees are required to solicit and consider all comments received from the public and submit copies of the comments to the Executive Officer with the Annual Reports due each ~~November 30~~ December 15th. In response to public comments, the Permittees may modify reports, plans, or schedules prior to submittal to the Executive Officer.
61. In accordance with Water Code Section 13389, the issuance of Waste Discharge Requirements for this discharge is exempt from those provisions of CEQA contained in Chapter 3 (commencing with Section 21100), Division 13 of the California Public Resources Code.
62. The Regional Board has considered anti-degradation requirements, pursuant to 40 CFR 131.12 and State Board Resolution No. 68-16, for this discharge. The Regional Board finds that the Urban Runoff discharges regulated under this Order are consistent with the federal and state anti-degradation requirements and a complete anti-degradation analysis is not necessary. This Order requires the continued implementation of programs and policies to reduce the discharge of ~~p~~Pollutants in Urban Runoff. This Order includes additional requirements to control the discharge of ~~p~~Pollutants in Urban Runoff from "Significant Redevelopment," as defined in Section VIII.B.1.a., and "New Development," as defined in Section VIII.B.1.b.
63. The Regional Board has notified the Permittees and interested parties of its intent to issue Waste Discharge Requirements for Urban Runoff and has provided them with an opportunity to submit their written views and recommendations.
64. The Regional Board, in a public hearing, heard and considered all comments pertaining to the discharge of Urban Runoff and to the tentative requirements.

IT IS HEREBY ORDERED that the Riverside County Flood Control and Water Conservation District, the County of Riverside, and the incorporated cities of Beaumont, Calimesa, Canyon Lake, Corona, Hemet, Lake Elsinore, Moreno Valley, Murrieta, Norco, Perris, Riverside, and San Jacinto, in order to meet the provisions contained in Division 7 of the Water Code and regulations adopted thereunder, and the provisions of the CWA, as amended, and the regulations and guidelines adopted there under, shall comply with the following:

I. RESPONSIBILITIES:

A. Responsibilities of the Principal Permittee:

1. The Principal Permittee shall be responsible for managing the overall Urban Runoff program and shall:
 - a. Coordinate revisions to the DAMP.
 - b. Implement management programs, monitoring and reporting programs, and related plans as required by this Order.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 19 of 4246

- c. ~~Coordinate~~ conduct chemical and biological water quality monitoring and hydrographic monitoring as required by the Executive Officer.
 - d. Conduct inspections and maintain the MS4 facilities over which it has jurisdiction.
 - e. Within 12 months of adoption of this Order, the Principal Permittee shall develop and maintain a Local Implementation Plan (LIP) that specifies how each applicable program element of the DAMP shall be implemented within its facilities. The Principal Permittee's LIP shall identify and describe the basis for those program elements that are not applicable to its facilities and activities. The LIP shall describe the plans, policies, procedures, and tools (e.g., checklists, forms, educational materials, etc.) used to execute the DAMP and comply with this Order. As the District is not a general purpose government, it does not have the authority to adopt ordinances. The LIP shall identify the organizational units responsible for implementation of each program element, shall establish internal reporting requirements to ensure and promote accountability, and shall describe an adaptive method of evaluation and assessment of program effectiveness for the purpose of identifying program improvements.
 - f. Review and revise, if necessary, those agreements to which it is a party and those regulations and policies it deems necessary to provide adequate legal authority to maintain the MS4 facilities for which it has jurisdiction and to take those actions required of it by this Order and the Federal Storm Water Regulations (see Section V—"Legal Authority/Enforcement", below);
 - g. To cause appropriate enforcement actions against ~~illegal~~ Discharges to the MS4 facilities for which it has jurisdiction be taken and pursued as necessary to ensure compliance with ~~Urban Runoff~~ storm water management programs, implementation plans, and regulations and policies, including physical elimination of ~~undocumented connections and IC/ID~~ illegal discharges (see Section VI—"Legal Authority/Enforcement", below);
 - h. Continue to Respond or cause the appropriate entity or agency to respond to ~~"Emergency Situations"~~ "Emergency Situations" (as defined in Appendix 4, Glossary) such as accidental spills, leaks, and ~~IC/ID~~ illegal discharges/illicit connections to prevent or reduce the discharge of ~~pollutants~~ Pollutants to its MS4 facilities and to the Waters of the U.-S.
 - i. Prepare, coordinate the preparation of, and submit to the Executive Officer, those reports and programs necessary to comply with this Order.
2. The activities of the Principal Permittee should also include, but not be limited to, the following:
- a. Provide staff support to the Establish a Management Steering Committee (the "Management Steering Committee" and as defined in Appendix 4, Glossary) as described in the ROWD to address Urban Runoff management policies for the

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 20 of 4246

Permit Area and coordinate the review, and necessary revisions to the DAMP and Implementation Agreement. The Management Steering Committee will continue to meet at least quarterly or more frequently as determined by the chairperson.

- b. Coordinate and conduct Technical Committee (the "Technical Committee" and as defined in Appendix 4, Glossary) meetings, at least ten times per year. The Technical Committee shall continue to direct the development of the DAMP, and coordinate the implementation of the overall Urban Runoff program, ~~as described in the ROWD. The Technical Committee will consist of one or more representatives from each Permittee.~~
- c. Will take the lead role in initiating and developing area-wide programs and activities necessary to comply with this Order.
- d. Coordinate activities and participate in committees/subcommittees formed to comply with this Order.
- e. Coordinate the implementation of this Order with the Regional Board and Co-Permittees ~~the implementation of this Order~~, including the submittal of all reports, plans, and programs as required under this Order.
- f. Provide technical and administrative support to the Co-Permittees, including informing them of the status of known pertinent municipal programs, pilot projects, and research studies.
- g. Coordinate with the Co-Permittees the implementation of Urban Runoff quality management programs, monitoring and reporting programs, implementation plans, public education, other ~~p~~Pollution ~~p~~Prevention measures, household hazardous waste collection, and ~~all~~BMPs outlined in the DAMP and take other actions as may be necessary to meet the MEP.
- h. Gather and disseminate information on the status of statewide Urban Runoff programs and evaluate the information for potential use in the execution of this Order. Hold workshops focused on Urban Runoff regulatory requirements, BMPs, and other related topics.
- i. Compile information provided by the Co-Permittees and determine their effectiveness in attaining Receiving Water qQuality sStandards. This determination shall include a comparative analysis of monitoring data to the applicable ~~w~~Water qQuality eObjectives for Receiving Waters as specified in Chapter 4 of the Basin Plan. A ~~p~~Pollutant source investigation and control plan shall be performed when elevated ~~p~~Pollutant levels are identified.
- j. Solicit and coordinate public input for major changes to the Urban Runoff management programs and the implementation thereof.
- k. Coordinate the development and implementation of procedures, and performance standards, to assist in the consistent implementation of BMPs to

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 21 of 4246

the MEP, as well as Urban Runoff management programs, among the Co-Permittees.

Participate in watershed management programs and regional and/or statewide monitoring and reporting programs.

B. Responsibilities of the Co-Permittees:

1. Each Co-Permittee shall be responsible for managing the Urban Runoff program within its jurisdiction and shall:

- ~~4.a.~~ Continue to maintain adequate legal authority to control the contribution of ~~p~~Pollutants to their MS4s and enforce those authorities.
- b. Conduct inspections of and maintain its MS4 facilities in accordance with the criteria developed pursuant to Section XII, CD, below.
- c. Continue to implement management programs, monitoring and reporting programs, ~~all appropriate~~ BMPs listed in the DAMP, and related plans as required by this Order and take such other actions as may be necessary to meet the MEP standard.
- d. Continue to seek sufficient funding for the area-wide Urban Runoff management plan, local Urban Runoff program management, Urban Runoff enforcement, public outreach and education activities and other Urban Runoff-related program implementation.
- e. Continue to coordinate among their internal departments and agencies, as appropriate, to facilitate the implementation of this Order and the DAMP.
- f. Continue to pursue enforcement actions as necessary within its jurisdiction for violations of Storm Water Ordinances, and other elements of its Urban Runoff management program.
- g. Respond to or arrange for the appropriate entity or agency to respond to ~~e~~Emergency ~~s~~Situations such as accidental spills, leaks, IC/IDs ~~illegal discharges/illicit connections~~, etc. to prevent or reduce the discharge of ~~p~~Pollutants to their MS4 facilities and the Waters of the U.S.
- h. Within 12 months of adoption of this Order, the Co-Permittee shall each develop and maintain a LIP that specifies how each program element of the DAMP shall be implemented within its jurisdiction. The LIP shall describe the ordinances, plans, policies, procedures, and tools (e.g., checklists, forms, educational materials, etc.) used to execute the DAMP and comply with this Order. The LIP shall identify the organizational units responsible for implementation of each program element, establish internal reporting requirements to ensure and promote accountability, and describe an adaptive method of evaluation and assessment of program effectiveness for the purpose of identifying program improvements.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 22 of 4246

2. The Co-Permittees' activities should include, but not be limited to, the following:

- a. Participate in the Management Steering Committee and the Technical Committee in accordance with Section XV.C.III.D. of this Order.
- b. Conduct and coordinate with the Principal Permittee surveys and monitoring needed to identify pollutant sources and drainage area characteristics.
- c. Prepare and submit reports to the Principal Permittee and/or the Regional Board in a timely manner.
- d. Review, comment, approve, and implement plans, strategies, management programs, monitoring and reporting programs, as developed by the Principal Permittee, Technical Committee, or the Management Steering Committee to comply with this Order.
- e. Participate in subcommittees formed by the Principal Permittee, Technical Committee, or the Management Steering Committee to comply with this Order.
- f. Submit up-to-date MS4 facility maps to the Principal Permittee. If necessary, these maps should be revised on an annual basis and the revised maps should be submitted to the Principal Permittee with the information required for preparation of the Annual Report.
- g. Prepare and submit to the Principal Permittee in a timely manner specific reports/information, related to the Co-Permittees' Urban Runoff program, necessary to develop an Annual Report for submittal to the Executive Officer.

II. DISCHARGE LIMITATIONS/PROHIBITIONS:

- A. In accordance with the requirements of 40 CFR 122.26(d)(2)(i)(B) and 40 CFR 122.26(d)(2)(i)(F), the Permittees shall continue to prohibit IC/ID ~~illicit connections and illegal discharges~~ (n~~on~~-storm w~~ater~~) from entering their respective MS4s.
- B. The discharge of Urban Runoff from each Permittee's MS4 facilities to the Waters of the U.-S. containing pollutants that have not been reduced to the MEP is prohibited.
- C. The Permittees shall continue to effectively prohibit the discharge of n~~on~~-storm w~~ater~~, including those from public agency Permittee activities, into the their respective MS4s and to the Waters of the U.-S. unless such discharge is authorized by a separate NPDES permit or specifically allowed by the following provisions. Section XIII of this Order authorizes Permittee Non-storm Water discharges under following:
 1. Order No. R8-2003-0061, General Waste Discharge Requirements for Discharges to Surface Waters That Pose an Insignificant (De Minimus) Threat to Water Quality (General Permit-De Minimus Discharges) as amended by Order Nos. R8-2005-0041 and R8-2006-0004, and

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 23 of 4246

2. Order No. 2006-0008-DWQ (NPDES No. CAG990002), General NPDES Permit for Discharges from Utility Vaults and Underground Structures to Surface Waters (General Permit-Utility Vaults).

D. The Permittees need not prohibit the discharges identified below. ~~If, h~~However, if any of the following discharges are identified by either a Permittee or the Executive Officer as a significant source of ~~p~~Pollutants, coverage under an NPDES permit or ~~w~~Waste ~~e~~Discharge ~~r~~Requirements may be required.

1. Discharges covered by a NPDES permit, Waste Discharge Requirements, or waivers issued by the Regional or State Board. Unless a Permittee is the discharger, the Permittees shall not be responsible for any exceedances of Receiving Water Limitations associated with such discharges;
2. Discharges from potable water line flushing and other potable water sources;
3. Emergency water flows (i.e., flows necessary for the protection of life and property) do not require BMPs and need not be prohibited. However, appropriate BMPs shall be considered where practicable when not interfering with emergency public health and safety issues;
4. Discharges from landscape irrigation, lawn/garden watering and other irrigation waters;
5. Air conditioning condensate;
6. Diverted stream flows;
7. Rising ground waters and natural springs;
8. Groundwater infiltration (as defined in 40 CFR 35.2005(20)) and "uncontaminated pumped groundwater" (as defined in Appendix 4, Glossary);
9. Passive foundation drains;
10. Passive footing drains;
11. Water from crawl space pumps;
12. Non-commercial vehicle washing, (e.g. residential car washing (excluding engine degreasing) and car washing fundraisers by non-profit organization);
13. Flows from riparian habitats and wetlands;
14. Dechlorinated swimming pool discharges;
15. Waters not otherwise containing Wastes as defined in Water Code Section 13050 (d); and

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 24 of 4246

16. Other types of discharges identified and recommended by the Permittees and approved by the Regional Board.

E. The Regional Board may issue Waste Discharge Requirements for discharges exempted from NPDES requirements, such as agricultural irrigation waters, if identified to be a significant source of pollutants.

E.F. The Regional Board may add categories of non-Urban Runoff discharges that are not significant sources of pollutants or remove categories of non-Urban Runoff discharges listed in Section II.CD., above, based upon a finding that the discharges are a significant source of pollutants.

F.G. When types of discharges listed in Subsections II.C.2-16II.D.2 through II.D.16, above, are identified as a significant source of pollutants to the Waters of the U.S., a Permittee shall either: prohibit the discharge category from entering theirs MS4 or ensure that "structural" and "source eControl BMPs" and Treatment Control BMPs (as defined in Appendix 4, Glossary) are implemented to reduce or eliminate pollutants resulting from the discharge. The Permittees shall evaluate the permitted discharges, as listed in Subsection II.CD.1., above, to their MS4s to determine if any are a significant source of pollutants to their MS4s and notify the Executive Officer if any are a significant source of pollutants to their MS4s.

G.H. The Permittees shall continue to reduce the discharge of pollutants, including trash and debris, from their respective MS4s to Receiving Waters to the MEP.

H.I. Discharges from the MS4s shall be in compliance with the discharge prohibitions contained in Chapter 5 of the Basin Plan.

H.J. Discharge of Urban Runoff from thea Permittee's MS4 shall not cause or contribute to a condition of nuisance as the term is defined in Section 13050 of the Water Code.

III. RECEIVING WATER LIMITATIONS

A. Urban Runoff discharges from the Permittees' MS4s shall not cause or contribute to exceedances of Receiving Water quality standards (as defined by "beneficial uses" and "water quality objectives" in the Basin Plan and amendments thereto) for surface waters or ground waters.

B. The DAMP and its components shall be designed to achieve compliance with Receiving Water Limitations associated with discharges of Urban Runoff to the MEP. It is expected that compliance with Receiving Water Limitations will be achieved through an iterative process and the application of increasingly more effective BMPs.

C. The Permittees shall comply with Sections II and III of this Order through timely implementation of control measures and other actions to reduce pollutants in Urban Runoff in accordance with the DAMP and other requirements of this Order, including modifications thereto.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 25 of 4246

D. If exceedance(s) of Receiving wWater eQuality eStandards due to Urban Runoff discharges persist, notwithstanding implementation of the DAMP and other requirements of this Order, the Permittees shall assure compliance with Sections II.B and III of this Order by complying with the following procedure:

1. Upon a determination by either the Permittees or the Executive Officer that ~~at~~ the discharges from the MS4 ~~systems~~ ~~is~~ are causing or contributing to an exceedance of an applicable Water Quality Standard, the Permittees shall, within two (2) working days, provide oral or e-mail notice to Regional Board staff of the location within its jurisdiction where the exceedance occurred and describe the nature of the exceedance. Following oral or e-mail notification, a written report must be submitted to the Executive Officer within thirty (30) calendar days of becoming aware of the situation. The report submitted for review and approval shall, at a minimum, describe the BMPs that are currently being implemented and the additional BMPs that will be implemented to prevent or reduce those ~~p~~ Pollutants that are causing or contributing to the exceedance of the applicable Receiving wWater eQuality eStandards. Alternatively, if the exceedance ~~is~~ are due to discharges to the MS4 from activities or areas not under the jurisdiction of the Permittees, the Permittees shall provide documentation of ~~this~~ ~~ese~~ discharges in the subject report, consistent with Subsection III.D.6, below.
2. Determination of the effect of Urban Runoff discharges from the MS4s on Receiving Water eQuality eStandards shall include a comparative analysis of the Permittees' monitoring data to the applicable wWater eQuality eObjectives for the Receiving Waters specified in Chapter 4 of the Basin Plan for the Receiving Waters.
3. The Executive Officer may by written notice require modifications to the report, required by Subsection III.D.1, above. If required, such modifications shall be submitted within thirty (30) calendar days of receipt of said written notice.
4. Within ninety (90) calendar days following approval by the Executive Officer of the report required by Subsection III.D.1, above, the Permittees shall revise the DAMP and their monitoring and reporting programs to incorporate the approved modified or additional BMPs that have been or are to be implemented, and the implementation schedule.
5. The revised DAMP and monitoring program are to be implemented in accordance with the approved schedule.
6. If the exceedance ~~is~~ are solely due to discharges to the MS4 that are outside the Permittees jurisdiction or control, the Permittees shall, within two (2) working days of becoming aware of the situation, provide oral or e-mail notice to Regional Board staff of the determination of the exceedance and provide written documentation of these discharges to the Executive Officer within ten (10) calendar days of becoming aware of the situation.

~~a.7.~~ So long as the Permittees have complied with the procedures set forth above and are implementing the revised DAMP, the Permittees do not have to repeat the same procedure for continuing or recurring exceedances of the same

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 26 of 4246

Receiving Water Limitations unless the Executive Officer determines it is necessary to develop additional BMP's and provides written notice to the Permittees of this determination.

IV. IMPLEMENTATION AGREEMENT

~~Within six (6) months of this Order's adoption, the existing Implementation Agreement shall be revised to include the city of Murrieta. A copy of the signature page and revisions to the Agreement shall be included in the Annual Report.~~

No later than November 30th of each year, the Permittees shall evaluate their Urban Runoff management programs and the Implementation Agreement and determine the need, if any, for revision. The Annual Report shall include the findings of this review and a schedule for any necessary revision(s) to the Implementation Agreement.

V. LEGAL AUTHORITY/ENFORCEMENT:

A. The Permittees shall continue to maintain adequate legal authority to control the contribution of ~~p~~Pollutants to the MS4s and enforce those authorities.

~~B.A.~~ The Permittees shall continue to take appropriate enforcement actions against violators of their Storm Water Ordinances, in accordance with the Federal Storm Water Regulations (40CFR, Part 122.26(d)(2)(I)(A-F)), and adopted/established guidelines and procedures as described in Section 3.4 of the DAMPE/CS.

~~C.~~ Within six (6) months of this Order's adoption, the Permittees shall evaluate their ordinances, regulations, rules and codes to determine if it has provided its staff authority to impose administrative fines for violations of its Storm Water Ordinance.

~~D.A.~~ Co-Permittees' Storm Water ~~e~~Ordinances or other local regulatory procedures shall include sanctions to ensure compliance. Sanctions shall include but shall not be limited to: verbal and/or written warnings, notice of violation or non-compliance, obtaining an administrative compliance, stop work or cease and desist order, a civil citation or injunction, the imposition of monetary penalties or criminal prosecution (infraction or misdemeanor). If the Co-Permittee's current ordinances or codes do not provide for the imposition of these civil or criminal penalties for violations of its Storm Water Ordinances, the Co-Permittee shall enact such ordinances within eighteen (18) months of this Order's adoption.

~~E.A.~~ The Permittees shall continue to provide notification of the need for follow-up action by ~~te~~ Regional Board staff regarding Urban Runoff related information gathered during site inspections of construction, and industrial sites regulated by the General Storm Water General Permits ~~or San Jacinto Watershed Construction Activities Permit~~ and at sites that should be regulated under these ~~p~~Permits. The notification should include ~~perceived~~observed violations of these ~~permits~~the Storm Water General Permits, prior history of violations of the Co-Permittee's Storm Water Ordinance, enforcement actions related to the Storm Water Ordinance taken by the Co-Permittee, and other relevant information. In addition, Sections IX, ~~X~~, and XII of this Order address additional notification requirements for construction, industrial and commercial sites not covered

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 27 of 4246

under the General Storm Water General Permits. The Regional Board shall be responsible for follow-up actions related to enforcement of the Storm Water General Permits.

~~E. Within twelve (12) months of this Order's adoption, and annually thereafter in November, the Permittees shall provide a report containing a review of their Storm Water Ordinances and their ordinance enforcement practices to assess their effectiveness in prohibiting non-exempt, non storm water discharges to the MS4s (the Permittees may propose appropriate control measures in lieu of prohibiting these discharges, where the Permittees are responsible for ensuring that dischargers adequately maintain those control measures). At a minimum, the following types of non-exempt, non-storm water discharges and wastes shall be considered:~~

- ~~1. Sewage, where a Co-Permittee operates a POTW and associated sewage collection system;~~
- ~~2. Wash water resulting from the hosing or cleaning of gas stations, and other types of automobile service stations;~~
- ~~3. Discharges resulting from the cleaning, repair, or maintenance of equipment, machinery, or facilities, including motor vehicles, concrete mixing equipment, portable toilet servicing, etc.;~~
- ~~4. Wash water from mobile auto detailing and washing, steam and pressure cleaning, carpet cleaning, etc.;~~
- ~~5. Water from cleaning of municipal, industrial, and commercial areas including parking lots, streets, sidewalks, driveways, patios, plazas, work yards and outdoor eating or drinking areas, containing chemicals or detergents, and without prior sweeping, etc.;~~
- ~~6. Runoff from material storage areas or uncovered receptacles that contain chemicals, fuels, grease, oil, or other hazardous materials;~~
- ~~7. Discharges of runoff from the washing of toxic materials from paved or unpaved areas;~~
- ~~8. Discharges from pool or fountain water containing chlorine, biocides, or other chemicals; pool filter backwash containing debris and chlorine;~~
- ~~9. Pet waste, yard waste, debris, sediment, etc.;~~
- ~~10. Restaurant or food processing facility wastes such as grease, floor mat and trash bin wash water, food waste;~~

~~G. Within eighteen (18) months of this Order's adoption, each Permittee shall submit a statement (signed by its legal counsel) that the Permittee has obtained all necessary~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 28 of 4246

~~legal authority to comply with this Order through adoption of ordinances and/or municipal code modifications.~~

VI. ILLICIT CONNECTIONS/ILLEGAL DISCHARGES; LITTER, DEBRIS AND TRASH CONTROL

- A. The Co-Permittees shall continue to prohibit ~~IC/ID~~illicit connections and illegal discharges to the MS4s through their Storm Water Ordinances and the Principal Permittee shall do so through its statutory authority. In addition, the Permittees shall continue to implement and improve routine inspection and monitoring and reporting programs for their MS4s. If routine inspections or dry weather monitoring indicate ~~IC/ID~~illicit connections or illegal discharges, they shall be investigated and eliminated or permitted within sixty (60) calendar days of receipt of notice by its staff or from a third "party" (as defined in Appendix 4, Glossary). ~~A summary of these actions shall be submitted annually beginning with the 2003-2004 Annual Report.~~
- B. The Permittees upon being put on notice by staff or a third pParty shall immediately upon becoming aware of the circumstances (within 24 hours of receipt of notice by its staff or from a third pParty) investigate all spills, leaks, and/or iIllegal eDischarges to the MS4s. Based upon their assessment and as specified below, the Permittees shall provide notifications and reporting as described in sSection 4 of the DAMP.

B. follows:

1. All discharges that endanger human health or the environment:

~~a. By phone to the Office of Emergency Services (the "OES") at (800-852-7550) and to the Executive Officer at (909-782-3238). Alternatively, the report to the Executive Officer may be done by e-mail at (sw@rb8.swrcb.ca.gov).~~

~~b. At a minimum, any sewage spill above 1,000 gallons or that could impact water contact recreation, any oil spill that could impact wildlife, any hazardous material spill where residents are evacuated, any spill of reportable quantities of hazardous waste (as defined in 40CFR 117 and 40 CFR 302), or any other spill or discharge that is reportable to the OES (collectively, an "Emergency Situation") shall be reported within twenty-four (24) hours of becoming aware of the circumstances.~~

~~2. Other spill incidents, including any unauthorized discharge, that are not incidents reportable to the OES shall be reported to the Executive Officer within two (2) business days of becoming aware of the circumstances.~~

~~3. A written report of the discharge or incident described in this subsection shall be submitted to the Executive Officer within ten (10) calendar days of becoming aware of the circumstances.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 29 of 4246

~~4. The Permittees may propose a reporting program, including reportable incidents and quantities, jointly with other agencies such as the County Health Department for approval by the Executive Officer.~~

~~C. The Permittees shall continue to implement control measures to reduce and/or to eliminate the discharge of pollutants, including trash and debris, from MS4s to the Receiving Water. These control measures shall be reported in the Annual Report.~~

~~D. Within eighteen (18) months of this Order's adoption, the Technical Committee shall provide a written assessment of the relative efficiency and cost effectiveness of the available BMPs and the BMPs currently implemented for the control of anthropogenic litter (e.g. street sweeping, catch basin cleaning, deployment of trash receptacles, public education, etc.) and develop recommendations for improving the effectiveness of the currently implemented measures, and implement appropriate BMPs to control trash in Urban Runoff. The Permittees are required to establish a system to record visual observation information regarding the materials collected from the MS4 (e.g. paper, plastic, wood, glass, vegetative litter, and other similar debris), descriptions of its main source(s) (e.g. office, residential, commercial, and industrial waste), and problem areas. The findings of this review, along with supporting field data, shall be included in the Annual Report for 2004-2005.~~

~~E. Within eighteen (18) months of this Order's adoption, the Permittees shall review their litter/trash control ordinances to determine the need for revision to improve the effectiveness of these ordinances. The findings of this review shall be included in the Annual Report for 2003-2004.~~

VII. SEWAGE SPILLS, INFILTRATION INTO THE MS4 SYSTEMS FROM LEAKING SANITARY SEWER LINES, SEPTIC SYSTEM FAILURES, AND PORTABLE TOILET DISCHARGES

~~The Executive Officer will request the local sewerage agencies to take the lead and develop unified response guidance, in cooperation with the Principal Permittee. The Principal Permittees shall continue to work collaborate with the local sewerage agencies to implement the develop a unified response procedure for responding to sewage spills that may have an impact on Receiving Water quality, including. The Permittees shall providing local sanitation districts 24-hour access to the MS4s to address sewage spills. The Permittees shall continue to work cooperatively with the local sewerage agencies to determine and control the impact of infiltration from leaking sanitary sewer systems on Urban Runoff quality.~~

~~B. Within twelve (12) months of this Order's adoption, the Permittees, whose jurisdictions have 50 or more septic tank sub-surface disposal systems in use, shall identify with the appropriate governing agency a procedure to control septic system failures to prevent impacts on Urban Runoff quality and continue to follow procedures established by the State Health Department to address such failures.~~

~~C. Within twelve (12) months of this Order's adoption, the Principal Permittee shall review the Permittees' current oversight programs for portable toilets to determine the need for revisions.~~

VIII. NEW DEVELOPMENT (INCLUDING SIGNIFICANT REDEVELOPMENT)

A. GENERAL REQUIREMENTS:

1. Each Co-Permittee shall, consistent with the DAMP and its Storm Water Ordinance, and any revisions thereto as required by this Order, when considering any map or permit for which ~~a~~Discretionary Project pursuant to California Public Resources Code Section 21065 and 21080(a) and Section 15357 of the Guidelines for CEQA, ~~shall approval is sought~~ require that said map or permit contain a condition requiring the applicant ~~such project~~ to obtain coverage under the General Permit-Construction Activity Storm Water Permit or the San Jacinto Watershed Construction Activities Permit, if applicable (collectively the "Construction Activity Permits"), by filing a Notice of Intent ("NOI") with either the State or Regional Board, as applicable. ~~Verification that said condition has been satisfied may be established, as to the General Construction Activity Storm Water Permit, by presentation of a letter from the State Board indicating that the required fees have been paid and a waste discharge identification number ("WDID No.") has been issued or determining from the State Board's web site that the WDID No. has been issued, and, as to the San Jacinto Watershed Construction Activities Permit, that the required Storm Water Pollution Prevention Plan ("SWPPP") has been approved, fees have been paid and the Regional Board has issued a WDID No. Within six (6) months of this Order's adoption, each Co-Permittee shall review and revise as needed its land use approval process to include a procedure to ensure that coverage has been secured under the appropriate Construction Activity Permit for each map or permit that it has approved.~~
2. Each Co-Permittee shall continue to implement those BMPs identified in ~~s~~Section 6 of the "New Development Guidelines", and the attachment thereto entitled "Selection and Design of Storm Water Quality Controls," that constitute Supplement A ("Supplement A") to the DAMP in its review of any map or permit for which discretionary approval is sought. The land use approval process of each Co-Permittee shall continue to require ~~s~~Source ~~e~~Control BMPs and address the need for structural ~~t~~Treatment Control BMP's, identify their location, and identify how long-term maintenance responsibilities are to be met.
3. The Permittees shall review and revise, as necessary, ~~s~~Sections 6 and 7 of the DAMP, including Supplement A, in order to effect the implementation of new or enhanced BMPs that more effectively reduce ~~p~~Pollutants in runoff from construction sites during all phases of construction, including post-construction. At a minimum, the DAMP shall continue to:
 - a. Discuss possible amendments to the Co-Permittees' ordinances, regulations, and codes that would enhance grading and erosion control and public education,
 - b. Propose review criteria to be applied in land use review processes to better address issues regarding Urban Runoff; and

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 31 of 4246

- c. Identify BMPs or regional or sub-regional Urban Runoff treatment/infiltration BMPs that would enhance ~~p~~Pollution ~~p~~Prevention measures and address post-construction Urban Runoff issues.
4. The Permittees shall review and revise, as necessary, ~~s~~Sections 6 and 7 of the DAMP, including Supplement A, in order to develop and effect the implementation of new or enhanced BMPs that reduce ~~p~~Pollutants in Urban Runoff from commercial and industrial sites both during and after site construction. Appropriate BMPs will be required for industrial/commercial land uses that are identified during the land use approval process. For industrial/commercial land uses that are identified subsequent to the issuance of a discretionary map or permit, appropriate BMPs will be addressed through ~~s~~Section 6 of the ~~DAMPE/CS~~. At a minimum the DAMP shall continue to address:
 - a. The identification of those characteristics of the development of a commercial or industrial site that are likely to be a source of ~~p~~Pollutants in Urban Runoff that should be addressed and considered during the land use approval process, and
 - b. The identification of regional or sub-regional Urban Runoff treatment/infiltration BMPs that would address post-construction Urban Runoff issues.
 5. Each Co-Permittee shall continue to reduce to the MEP the short and long-term impacts on Receiving Water quality from New Developments, as defined in Subsection B.1, below, and Significant Redevelopment, as defined in Subsection B.1, below, as required in Subsection B., below. In order to reduce pollutants and runoff flows from New Development and Significant Redevelopment to the MEP, the Co-Permittees shall at a minimum:
 - a. Review their respective land use approval and CEQA review processes to insure that each addresses Urban Runoff issues consistent with provisions of this Order and make appropriate revisions to each, and
 - b. Develop and implement a public/business education program as specified in Section ~~IX.c.7, IX.C.4.,~~ below.
 6. Each Co-Permittee shall provide the Regional Board with any draft general plan or any draft general plan amendments for comment in accordance with Government Code Section 65350 et. seq.
 7. Each Co-Permittee shall, through its conditions of approval, continue to address the maintenance and operation of ~~s~~Structural BMPs required to be constructed to ensure Urban Runoff quality from New Development. The parties responsible for the maintenance and operation of such ~~s~~Structural BMPs and an appropriate funding mechanism shall be identified in said conditions of approval.
 8. The Co-Permittees shall continue to implement the BMPs described in ~~s~~Section 6 of the ~~DAMP~~.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 32 of 4246

B. WATER QUALITY MANAGEMENT PLAN FOR URBAN RUNOFF (FOR NEW DEVELOPMENT/SIGNIFICANT REDEVELOPMENT)

~~Within twenty (20) months of this Order's adoption, each the Co-Permittees shall develop a~~ include in its LIP a list of project categories over which the Co-Permittee has only ministerial authority (Ministerial Projects) under its laws and ordinances as addressed in California Public Resources Code Section 21080(b)(1) and Sections 15022 (a) (1) (B), 15268(c) of the Guidelines for CEQA.

The Permittees shall continue to implement the approved Water Quality Management Plan (the "WQMP") for Discretionary Projects as described in ~~s~~Section 6 of the DAMP. The WQMP ~~identifying~~ identifies BMPs, including Site ~~d~~Design standards for ~~s~~Source ~~e~~Control and structural Treatment Control BMPs⁹, (as defined in Appendix 4, Glossary) that are to be applied when considering any map or permit for which ~~d~~Discretionary Project approval is sought. The WQMP is ~~intended to address~~ regional and sub-regional source Treatment ~~e~~Control and structural BMPs and ~~to provide~~ guidelines for site specific, "post-construction BMPs" (as defined in Appendix 4, Glossary) to address management of Urban Runoff quantity and quality. The WQMP is ~~to be submitted to the Executive Officer for his review and approval, consistent with the criteria identified in Subsections B.1., 2., and 3., below:~~

1. The WQMP ~~shall address~~ management of Urban Runoff quality from a project site, represented by a map or permit for which discretionary approval is sought from a Co-Permittee, in one of the categories of development identified below:
 - a. "Significant Redevelopment" is defined as the addition or creation of 5,000, or more, square feet of impervious surface on an existing developed site. This includes, but is not limited to, construction of additional buildings and/or structures, extension of the existing footprint of a building, construction of impervious or compacted soil parking lots. Where Significant Redevelopment results in an increase of less than fifty percent of the existing impervious surfaces of an existing developed site, and the existing developed site received its discretionary land use approvals prior to the adoption of the WQMP, the WQMP ~~would apply~~ only to the addition, and not the existing development. Significant Redevelopment does not include routine maintenance activities that are conducted to maintain original line and grade, hydraulic capacity, the original purpose of the constructed facility or emergency actions required to protect public health and safety;
 - b. For purposes of this Order, the categories of development identified below, shall be collectively referred to as "New Development":
 - ~~1~~(1) Residential development of 10 dwelling units, or more, including single family and multi-family dwelling units, condominiums, or apartments.
 - ~~2~~(2) Industrial and commercial development where the land area represented by the proposed map or permit is 100,000 square feet, or more, including, but not limited to, non-residential developments such as hospitals,

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 33 of 4246

educational institutions, recreational facilities, mini-malls, hotels, office buildings, warehouses, light industrial, and heavy industrial facilities;

~~3.~~(3) Automotive repair shops (with standard industrial classification ("SIC") codes 5013, 7532, 7533, 7534, 7537, 7538, and 7539).

~~4.~~(4) Restaurants (SIC Code 5812) where the project site is 5,000 square feet, or more.

~~5.~~(5) Hillside development that creates 10,000 square feet, or more, of impervious surface(s), including developments located on areas with known erosive soil conditions or where the natural slope is twenty-five percent or more.

~~6.~~(6) Developments creating 2,500 square feet, or more, of impervious surface that is adjacent to (within 200 feet) or discharging directly into areas designated in the Basin Plan as waters supporting habitats necessary for the survival and successful maintenance of plant or animal species designated under state or federal law as rare, threatened, or endangered species (defined in the Basin Plan as "RARE") or waterbodies listed on the CWA Section 303(d) list of Impaired Waterbodies within the Permit Area.

~~7.~~(7) Parking lots of 5,000 square feet or more of impervious surface exposed to storm water. Parking lot is defined as a site or facility for the temporary storage of motor vehicles.

c. The primary objective of the WQMP, by addressing Site Design, sSource eControl and structuralTreatment Control BMPs applied on a regional, sub-regional or site specific basis, is to ensure that the land use approval process of each Co-Permittee will minimize pPollutant loads in Urban Runoff from project sites for a map or permit for which discretionary approval is given.

~~2. This objective may be achieved through source control and structural BMPs. In developing the WQMP, the Permittees are to consider and address the following:~~

~~a. Pollutants of Concern/Conditions of Concern. The WQMP is to include a protocol by which Pollutants of Concern and/or Conditions of Concern are identified and their potential impact on Urban Runoff from a project site that is to be developed by one or more of the categories specified in Section VIII.B.1., above. The protocol shall include, at a minimum, consider_ation of the following:~~

~~(1) The quality of the Receiving Waters in proximity to the project site (including pollutants for which a waterbody within the Permit Area that has been listed as impaired under CWA Section 303(d));~~

~~(2) The category of development and the type of pollutants associated with that development category;~~

~~(3) Pollutants expected to be present on the project site; and~~

~~(4) Sensitivity of the Receiving Waters in proximity to the project site to changes in storm water discharge flow rates, velocities, durations, and volumes.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 34 of 4246

~~b. Implementation Process. The WQMP shall specify at which point in the land use approval process the provisions of the WQMP should be considered. The WQMP shall generally describe the type of municipal departments or related agencies that are best equipped to evaluate the project site and draft the conditions of approval that will identify the types of BMPs required to address the specified concerns indicated by the protocol developed consistent with Subsection B.2.a, above, and incorporated into the WQMP.~~

~~If the draft condition of approval identifies the need for source control or structural BMPs⁹, the WQMP will require the proposed condition of approval to identify the operation and maintenance requirements for the identified structural source and/or treatment control and identify the funding source(s) and the parties responsible for the ongoing operation, maintenance, repair, rehabilitation and/or replacement of the source control and/or structural BMPs⁹.~~

~~c. The WQMP shall include a list of recommended source control and structural BMPs⁹ and a protocol, developed pursuant to Subsection B.2., above, that will identify those applications that would be most effective for a project site that is to be developed by one or more of the categories specified in Section VIII.B.1., above. The source control and structural BMPs included in said list shall, at a minimum:~~

~~e. Control the post construction peak storm water runoff discharge rates and velocities to avoid increasing downstream erosion beyond pre construction conditions;~~

~~g. Conserve natural areas and protect stream habitat, where feasible;~~

~~i. Minimize the introduction of Pollutants of Concern into Urban Runoff;~~

~~k. Remove Pollutants of Concern from Urban Runoff to the MEP;~~

~~m. Protect slopes and channels from eroding;~~

~~o. Require storm drain inlet stenciling and signage;~~

~~q. Require properly designed outdoor material storage areas;~~

~~s. Require properly designed trash storage areas; and~~

~~u. Be located as close to pollutant sources, as appropriate and economically/technologically feasible, and before the Urban Runoff is discharged into Receiving Waters.~~

~~0. If by January 1, 2005, the Permittees have not developed the WQMP and/or the WQMP has not been approved by the Executive Officer, then each Co Permittee shall cause to be placed on any proposed project submitted to it after said January~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 35 of 4246

~~1st that requires discretionary approval of a map or permit that proposes to develop a site consistent with one or more of the categories specified in Subsection B.1., above, conditions of approval that will require source control and/or structural BMPs that are to meet design standards consistent with those specified in Subsection B.5, below.~~

~~0. Source control and structural BMPs for any proposed project submitted to a Co-Permittee that requires discretionary approval of a map or permit that proposes to develop a site consistent with one or more of the categories specified in Subsection B.1., above, are to be sized to comply with one of the following numeric sizing criteria or be determined by the Co-Permittee to provide equivalent or superior treatment of Urban Runoff, on a site basis:~~

~~aa. Volume. Volume based BMPs shall be designed to treat urban pollutants (including, but not limited to, sediments, copper, lead, arsenic, zinc, and pesticides), or infiltrate either:~~

- ~~29) The volume of Urban Runoff produced from a 24 hour, 85th percentile storm event, as determined from the local historical rainfall record; or~~
- ~~30) The volume of annual Urban Runoff produced from a 24 hour, 85th percentile rainfall event, determined as the maximized capture Urban Runoff volume for the area, from the formula recommended in *Urban Runoff Quality Management, WEF Manual of Practice No. 23/ASCE Manual of Practice No. 87 (1998)*; or~~
- ~~31) The volume of annual Urban Runoff based on unit basin storage volume, to achieve 80% or more volume treatment by the method recommended in *California Storm Water Best Management Practices Handbook - Industrial/Commercial (1993)*; or~~
- ~~32) The volume of Urban Runoff, as determined from the local historical rainfall record, that achieves approximately the same reduction in pollutant loads and flows as achieved by mitigation of the Urban Runoff produced from a 24 hour, 85th percentile storm event;~~

~~Or,~~

~~jj. Flow. Flow based BMPs shall be designed to treat urban pollutants (including, but not limited to, sediments, copper, lead, arsenic, zinc, and pesticides), or infiltrate either:~~

- ~~38) The maximum flow rate of Urban Runoff produced from a rainfall intensity of 0.2 inch of rainfall per hour; or~~
- ~~39) The maximum flow rate of Urban Runoff produced by the 85th percentile hourly rainfall intensity, as determined from the local historical rainfall record, multiplied by a factor of two; or~~
- ~~40) The maximum flow rate of Urban Runoff, as determined from the local historical rainfall record, that achieves approximately the same reduction in pollutant loads and flows as achieved by mitigation of the 85th percentile hourly rainfall intensity multiplied by a factor of two.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 36 of 4246

2. Implementation of ~~the WQMP Subsections B.1. through B.5., above~~ shall include consideration of the following:
 - a. ~~Each Co-Permittee may propose equivalent sizing criteria for Treatment Control~~~~structural~~ BMPs that will achieve greater or substantially similar ~~p~~Pollution control benefits. In the absence of approved equivalent sizing criteria, the Co-Permittee shall implement the ~~above stated~~ sizing criteria ~~specified in sSection 6 of the DAMP.~~
 - b. Waiver Provisions. A Co-Permittee may provide for a project to be waived from the requirement of implementing ~~Treatment Control~~~~structural~~ BMPs (~~Section VIII. B. 5~~)~~in conformance with Section 7 of the approved WQMP.~~ All waivers, along with documentation justifying the issuance of the waiver, must be submitted to Regional Board staff in writing within thirty (30) calendar days. If the Executive Officer determines that waivers are being inappropriately granted, this Order may be reopened to modify these waiver conditions:
 - (1) If infeasibility can be established. A waiver of infeasibility shall only be granted by a Co-Permittee when all available ~~Treatment Control~~~~structural~~ BMPs have been considered and rejected as technically infeasible and/or the cost of implementing the ~~structural~~ ~~Treatment Control~~ BMP greatly outweighs the ~~p~~Pollution control benefit.
 - (2) ~~For those portions of the Permit Area that will not result in a discharge to the Receiving Waters under the rainfall conditions specified in sSection 6 of the DAMP~~~~Subsections B.5., above.~~
 - c. If a particular BMP is not technically feasible, other BMPs should be implemented to achieve the same level of ~~p~~Pollution control or if the cost of implementing a technically feasible BMP greatly outweighs the ~~p~~Pollution control benefits, the Co-Permittees may grant a waiver of the numeric sizing criteria for said BMP as set forth in the WQMP.
 - d. The Principal Permittee and the Co-Permittees, individually or jointly, as appropriate, may develop and implement regional and sub-regional ~~watershed management~~ BMPs that address Urban Runoff from New Development and Significant Redevelopment.
 - e. The obligation to install ~~structural~~ ~~Treatment Control~~ BMPs for New Development will be satisfied if, for a specific plan, multiple subdivisions, or a regional area, ~~structural~~ ~~Treatment Control~~ BMPs are constructed with the requisite capacity to serve the specific plan, multiple subdivisions, or regional area, even if certain phases of the specific plan or the subdivision do not have ~~structural~~ ~~Treatment Control~~ BMP located within the boundaries of the particular phase, provided, however, the ~~structural~~ ~~Treatment Control~~ BMPs are designed and implemented to intercept Urban Runoff prior to it reaching the Receiving Waters and said BMPs meet the sizing criteria set forth in the WQMP ~~or as specified in Subsection B.5, above.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 37 of 4246

3. Structural Treatment Control BMPs utilizing infiltration [exclusive of incidental infiltration and BMPs not designed to primarily function as infiltration devices (such as grassy swales, detention basins, vegetated buffer strips, constructed wetlands, etc.)] shall comply with the following:
 - a. Infiltration shall not cause or contribute to an exceedance of groundwater Quality Objectives in groundwater.
 - b. Protect groundwater quality.
 - c. Should not be used in high vehicular traffic areas (25,000 or greater average vehicles daily) unless necessary to mitigate peak storm flows for the protection of real and personal property, or for the protection of public health and safety. A sampling and analysis plan shall be implemented for such sites.
 - d. Shall be located at least 500 feet horizontally from water supply wells.
 - e. Shall not cause a nuisance, including odor, vectors or pollution as defined by Water Code Section 13050.

IX. PERMITTEE MUNICIPAL INSPECTION PROGRAMS

The Permittee municipal inspection programs are outlined in Sections 7 and 8 of the DAMPE/CS, prepared by the Permittees. The E/CS describes minimum inspection and enforcement procedures utilizing existing inspection programs, provides criteria for characterizing the significance of violations, criteria for prioritizing violations, appropriate response actions corresponding to the priority of violations and identifies the hierarchy of enforcement/compliance responses. Section 3.4 of the DAMPE/CS comprises provides a framework to standardize the implementation and enforcement by the Co-Permittees of their respective Storm Water Ordinances. As part of the E/CS, the Principal Permittee and the County have implemented the CAP that, through the Riverside County Environmental Health Department, specifically addresses storm water compliance survey/inspections of each facility that must secure a hazardous materials permit for either storing, handling or generating hazardous materials and restaurants. The Co-Permittees shall continue to enforce their respective Storm Water Ordinances consistent with the DAMPE/CS and shall revise the E/CS, within twelve (12) months of the adoption of this Order, and their respective Storm Water Ordinances consistent with the program elements described below. The revision of the E/CS is to be submitted for approval, in writing, by the Executive Officer.

A. Construction Sites

~~17. Each Co-Permittee shall develop within twelve (12) months of this Order's adoption, an inventory of active construction sites within its jurisdiction for projects for which a building or grading permit has been issued for a site that is 1 acre or larger. As written in the "Storm Water Phase II Final Rule - Small Construction Program Overview" (EPA 833 f 00-013, January 2000, Fact Sheet 3.0), smaller parcels that are part of a larger development will also be required to comply with the Phase II rules. A construction site will be included in the inventory regardless of whether the construction site is subject to the Construction Activity Permits or other individual construction storm water NPDES permits. In addition, beginning thirteen months (13) from the adoption date of this Order, New Development/Redevelopment Sites meeting the criteria defined in Section VIII. B.1 shall also be included in this database. This inventory shall be routinely maintained to reflect additional construction sites as permits are issued and may reflect deletions as occupancy permits are issued or a construction site is abandoned. This inventory shall be maintained in a computer database system. An electronic copy or update of the database, in a format acceptable to the Executive Officer, shall be provided with each Annual Report or upon request. The database specifics shall at a minimum include the relevant site information as outlined in the E/CS. The revised E/CS should provide for the inclusion of the following information: facility name (dba), address, city, zip code, mailing address (if different), location reference (such as GIS coordinates, cross streets, etc.) facility contact and phone number, site size, Map/Plot Plan No., Grading Permit No., Assessor's Parcel Number ("APN"), and State WDID No. Linking the database to a Geographical Information System ("GIS") is recommended but is not required.~~

~~18. Within twelve (12) months of this Order's adoption, the Co-Permittees shall inspect all inventoried construction sites, document relevant site information as outlined in the E/CS, and shall cause said information to be entered into the inventory database. In establishing priorities for inspection of construction sites consistent with this Order, the Co-Permittees shall prioritize construction sites within their jurisdiction as a high, medium, or low threat to Receiving Water quality (consistent with the criteria contained in Section IX.A.3., below). Evaluation of construction sites should be based on such factors as soil erosion potential, project size, proximity and sensitivity of Receiving Waters, history of compliance, and other relevant factors. The priority level assigned to a construction site may change during the construction period, however, at a minimum, the following construction sites shall be given a high priority in the initial inventory:~~

~~19. Sites that disturb an area greater than 50 acres;~~

~~21. Sites that disturb an area greater than one (1) acre and are located adjacent to, within 200 feet, of an identified impaired water body within the Permit Area; and,~~

~~23. Sites that disturb an area greater than one (1) acre and directly discharge to an identified Impaired Waterbody within the Permit Area.~~

~~25. Each Co Permittee shall conduct construction site inspections for compliance with its ordinances, including its Storm Water Ordinance, regulations, codes, and the WQMP, when approved. Construction site inspections shall at a minimum address the following areas as outlined in the E/CS:~~

~~aa. Check for submittal of a NOIs in compliance with the Construction Activity Permits, if required;~~

~~cc. Confirm a SWPPP, if required, is on-site;~~

~~ee. Confirm compliance with the Co Permittee's Storm Water Ordinance;~~

~~gg. Check for active non-stormwater discharges or potential illicit connections or illegal discharges to a MS4; and,~~

~~ii. The frequency of inspections shall be as follows:~~

Site Priority Level	Inspection Frequency
High	Once every two weeks
Medium	Once each month
Low	Once during the wet season
Follow up inspections when Storm Water Ordinance violations are observed	As specified in the E/CS, at least within two weeks, or consistent with a compliance schedule.

~~53. Each Co Permittee shall enforce its Storm Water Ordinance at construction sites as necessary to maintain compliance with the E/CS and this Order. Sanctions for non-compliance may include: verbal and/or written warnings, notice of violation or non-compliance, obtaining an administrative compliance, stop work or cease and desist order, a civil citation or injunction, the imposition of monetary penalties or criminal prosecution (infraction or misdemeanor).~~

~~54. As described in the E/CS, the Co Permittees will provide training to staff involved in inspecting construction sites. Staff training will address the requirements of the following:~~

~~ddd. The Storm Water Ordinances, resolutions, and codes;~~

~~fff. This Order, the approved WQMP, and the DAMP;~~

~~hhh. The Construction Activity Permits;~~

~~jjj. The E/CS.~~

~~64. Construction site inspectors will also receive training regarding SWPPPs, selection and maintenance of appropriate BMPs for construction sites, including erosion and sediment control. Each Co-Permittee shall have arranged for adequate training of its current inspection staff within twelve (12) months of this Order's adoption and on an annual basis thereafter, prior to the start of the "Rainy Season" (October 1 through May 31st). Training programs should be coordinated with Regional Board staff and prior notification of formal classroom training activities shall be provided to Regional Board staff. New hires or transfers that will be performing construction site inspections for a Co-Permittee shall be trained within six (6) months of starting inspection duties.~~

~~65. Within twenty four (24) hours of receipt of notice by its staff or from a third party, each Co-Permittee shall continue to provide oral or e-mail notification to Regional Board staff of sites within its jurisdiction that are determined to be an Emergency Situation. Following oral or e-mail notification, a written report must be submitted to Regional Board Staff within ten (10) calendar days of receipt of notice of the Emergency Situation, detailing the nature thereof, corrective actions taken by the site owner, other relevant information (e.g., past history of non-compliance, environmental damage resulting from the Emergency Situation, site owner responsiveness) and the type of enforcement, consistent with Table 4 of the E/CS, that has been or will be carried out by the Co-Permittee. Further, incidences of non-compliance shall be recorded along with the information noted in the written report and the final outcome/enforcement for the incident will be included in the database identified in Subsection A.1, above.~~

~~66.1. If a Co-Permittee receives notice by its staff or from a third party of a non-Emergency Situation representing a possible violation of the General Permit-Construction Activity Permits or other order or permit issued by the State or Regional Board, the Co-Permittee shall, within two (2) working days, provide oral or e-mail notice to Regional Board staff of the location within its jurisdiction where the incident occurred and describing the nature of the incident. Following oral or e-mail notification, a written report must be submitted to the Regional Board staff within ten (10) calendar days of becoming aware of the situation.~~

~~9.2. Upon referral of a construction site to Regional Board staff for failure to obtain coverage under the applicable Construction Activity Permit, failure to keep a SWPPP at the construction site, if applicable, or an observed act or omission that suggests failure to comply with either, the Co-Permittee will take no further action at the construction site with regard to securing compliance with the General Permit-Construction Activity Permits. It is understood by the Co-Permittees and Regional Board staff that this will preclude duplication of effort and insure that consistent direction is provided to the owner/developer and the construction site manager as to what is required to bring the site into compliance with the General Permit-Construction Activity Storm Water Permit or San Jacinto Watershed Construction Activities Permit. Each Co-Permittee shall take appropriate actions to bring a construction site into compliance with its local ordinances, rules, regulations, and WQMP, when approved.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 41 of 4246

68. The number of inspections and the actions taken will be documented by the Co-Permittees and an appropriate summary of said actions will be provided to the Principal Permittee for inclusion in the Annual Report submitted to the Regional Board.

41.3. The Permittees need not inspect construction sites already inspected by Regional Board staff if the inspection of said site, given its prioritization consistent with Section 7 of the DAMPE/CS, was concluded within the time frame specified for said site's prioritization. To facilitate this, Regional Board staff will post a list of facilities inspected on the website or make this information available to the Co-Permittees by other pre-arranged means.

B. Industrial and Commercial Facilities

The Principal Permittee and the County have implemented the CAP that, through the Riverside County Department of Environmental Health, specifically addresses storm water compliance survey/inspections of food facilities and each business that must secure a hazardous materials permit for either storing, handling or generating hazardous materials. As described in Section 8 of the DAMPE, the Permittees must either participate in the CAP or implement an equivalent inspection program. The cities of Corona and Riverside maintain such programs through their respective POTW pre-treatment programs that may be supplemented by the activities of the Department of Environmental Health during routine inspections. The County is establishing a stand alone NPDES Stormwater Compliance Inspection and Enforcement Program (CIEP) for industrial/commercial facilities in the unincorporated areas of the County.

1. Each Co-Permittee shall ~~continue to maintain~~ develop within eighteen (18) months of this Order's adoption, an inventory of industrial and commercial facilities in the Permit Area within its jurisdiction that has the potential to discharge pollutants to the MS4.
 - a. ~~Each Co-Permittee that presently has an existing local industrial inspection program (the cities of Corona and Riverside as to their respective POTW pre-treatment inspections and the County through the CAP) shall include in their respective inventory of industrial facilities information derived from existing compliance survey and inspection programs.~~
 - b. ~~Each Co-Permittee without an industrial inspection program shall include in their inventory of industrial facilities information from the CAP that is relevant to its jurisdiction and may include information derived from other agencies providing services within its jurisdiction, including, but not limited to, the appropriate Fire Department, health departments, and POTW servicing the Permit Area.~~
 - c. ~~An industrial facility will be included in said inventory, regardless of whether the facility is subject to the General Industrial Activities Storm Water Permit, or other individual NPDES permits issued by the State or Regional Boards.~~
 - d. ~~The inventory shall be routinely updated, information can be derived from any of the following sources: conditional use permits, plot plans, building permits,~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 42 of 4246

~~business licenses, occupancy permits, hazardous materials permits, and hazardous waste generator permits are approved for the development of a new industrial facility, additional facilities are identified through the CAP, and as compliance surveys and inspections are completed and industrial facilities are identified. This inventory shall be maintained in a computer database system.~~

~~e. The Co-Permittees shall not issue an occupancy permit to an industrial facility or other license authorizing the facility to operate, unless the applicant is informed of the General Industrial Activities Storm Water Permit and that it may have to secure coverage thereunder.~~

~~f. The database information content may be Co-Permittee specific and shall be developed and maintained in accordance with the E/CS. The database contents shall at a minimum include the relevant site information, outlined in the E/CS. The revised E/CS should provide for the inclusion of the following information: facility name (dba), address, city, zip code, mailing address (if different), location reference (such as, GIS coordinates, cross streets, etc.) facility contact and phone number, SIC Code(s), State WDID No. (if any), APN, and site size. An electronic copy or update of the database, in a format acceptable to the Executive Officer, shall be provided with each Annual Report or upon request. Linking the database to a GIS is recommended but is not required.~~

~~2. The frequency and priority of an industrial/commercial facility compliance survey or inspection will be based on the most recent facility visit by the CAP or equivalent program as outlined in Section 8 of the DAMPE/CS, as revised, consistent with this Order. The revised E/CS shall prioritize industrial facilities within their jurisdiction as a high, medium, or low threat to water quality. Evaluation of these facilities should be based on such factors as type of industrial activities (SIC codes), materials or wastes used or stored outside, pollutant discharge potential, facility size, proximity and sensitivity of Receiving Waters, frequency of existing inspections, based upon other California statutes or regulations, or local regulations, ordinances, or codes, and any other relevant factors. At a minimum, a high priority classification shall be assigned to facilities subject to Section 313 of Title III of the Superfund Amendments and Reauthorization Act of 1986 and facilities with a high potential for or history of unauthorized, non-storm water discharges.~~

~~3.~~

~~4. Once the inventory required by Subsection B.1, above, has been completed and the industrial facilities have been prioritized, consistent with Subsection B.2, above, the Co-Permittees are to determine the frequency with which the inventoried facilities are surveyed or inspected. Unless inspected more frequently pursuant to the existing programs, those industrial facilities given a high priority are to be inspected at least once a year, those industrial facilities given a medium priority are to be inspected at least once biannually, and those industrial facilities given a low priority are to be inspected at least once during the term of this Order. In the event that the industrial facility is found to be in violation of the Co-Permittee's Storm Water Ordinances the frequency of inspection shall be increased consistent with a compliance schedule~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 43 of 4246

determined appropriate by the Co-Permittee and as outlined in the revised E/CS to cause said facility to be brought into compliance.

- ~~5.~~
- ~~6. Industrial facility compliance surveys and inspections shall at a minimum address the following, as outlined in the E/CS:~~
- ~~7.~~
- ~~8. Check for submittal of a NOI to comply with the General Industrial Activities Storm Water Permit or other permit issued by the State or Regional Board to an industrial facility within the Permit Area;~~
- ~~9.~~
- ~~10. Confirm compliance with the Co-Permittee's Storm Water Ordinance;~~
- ~~11.~~
- ~~12. Check for active non-storm water discharges, potential illicit connections, and illegal discharges to the MS4;~~
- ~~13.~~
- ~~14. Potential for discharge of pollutants in Urban Runoff from areas of material storage, vehicle or equipment fueling, vehicle or equipment maintenance (including washing), waste handling, hazardous materials handling or storage, delivery areas or loading docks, or other outdoor work areas;~~
- ~~15. Implementation and maintenance of appropriate BMPs for industrial facilities.~~
- ~~16.~~
- ~~17. Each Co-Permittee shall continue to enforce its ordinances, including its Storm Water Ordinance, resolutions and codes at industrial facilities as necessary to maintain compliance with this Order. Sanctions for non-compliance may include: verbal or written warnings, notice of violation or non-compliance, obtaining an administrative compliance, stop work, or cease and desist order, the imposition of monetary penalties or criminal prosecution (infraction or misdemeanor).~~
- ~~18.~~
2. Within twenty four (24) hours, each Co-Permittee shall continue to provide oral or e-mail notification to the Regional Board of facilities within its jurisdiction it perceives to be an illicit connection, illegal discharge, or that is determined to be an Emergency Situation. Following oral or e-mail notification, a written report must be submitted to Regional Board Staff within ten (10) calendar days of the Co-Permittee's receipt of notice of the Emergency Situation, detailing the nature of the Emergency Situation, corrective actions taken by the facility owner, other relevant information (e.g., past history of non-compliance with the Co-Permittee's Storm Water Ordinance, environmental damage resulting from the Emergency Situation, facility owner responsiveness) and the type of enforcement, consistent with Table 4 of the E/CS, that has been or will be carried out by the Co-Permittee. Further, incidences of non-compliance shall be recorded, along with the information noted in the written report and the final outcome/enforcement for the incident shall be included in the database identified in Subsection B.1, above.
3. If a Co-Permittee receives notice by its staff or from a third party of a non-Emergency Situation representing a possible violation of the General Permit-

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 44 of 4246

~~Industrial Activity Storm Water Permit or other permit issued by the State or Regional Board to an industrial facility, the Co-Permittee shall, within two (2) working days, provide written notice to Regional Board staff of the location within its jurisdiction where the incident occurred and describing the nature of the incident.~~

4. Upon referral of an industrial facility to Regional Board staff for failure to obtain coverage under the General ~~Permit-Industrial Activities Storm Water Permit~~, failure to keep a SWPPP at the industrial facility, or an observed act or omission that suggests failure to comply with either, the Co-Permittee will take no further action at the industrial facility with regard to securing compliance with the General ~~Permit-Industrial Activities Storm Water Permit~~. It is understood by the Co-Permittees and Regional Board staff that this will preclude duplication of effort and insure that consistent direction is provided to the facility owner/manager as to what is required to bring the facility into compliance with the General ~~Permit-Industrial Activities Storm Water Permit~~. Each Co-Permittee shall take appropriate actions to bring an industrial facility into compliance with its local ordinances, rules, regulations, and WQMP, ~~when approved.~~

~~9. The number of compliance surveys/inspections and the actions taken shall be documented by the Co-Permittees and an appropriate summary of said actions shall be provided to the Principal Permittee for inclusion in the Annual Report submitted to the Regional Board.~~

~~10. As described in the E/CS, the Co-Permittees shall provide training to staff that are involved in conducting compliance surveys/inspections of industrial facilities. Staff training will address the requirements of the following:~~

~~a. The Storm Water Ordinance~~

~~b. This Order and the DAMP~~

~~c. The General Industrial Activities Storm Water Permit and any other permit issued to industrial facilities within the Permit Area by the State or Regional Board; and~~

~~d. The E/CS.~~

~~11. Each Co-Permittee's staff assigned to conduct the industrial facilities compliance surveys/inspections will also receive training regarding pollution prevention plans and implementation of appropriate BMPs for industrial facilities. Training programs should be coordinated with Regional Board staff and prior notification of formal classroom training activities shall be provided to the Regional Board staff.~~

~~12. Each Co-Permittee shall have arranged for adequate training of its staff assigned to conduct the industrial facilities compliance surveys/inspections within eighteen (18) months of this Order's adoption, and on an annual basis thereafter. New hires or transfers that will be performing the industrial facilities~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 45 of 4246

~~compliance surveys/inspections for a Co-Permittee will be trained within six (6) months of starting field duties.~~

- ~~5. The Permittees need not inspect industrial or commercial facilities already inspected by Regional Board staff if the inspection of said site, given its prioritization consistent with section Section 8 of the DAMPE/CS, was concluded within the time frame specified for said site's prioritization. To facilitate this, Regional Board staff will post a list of facilities inspected on the website or make this information available to the Co-Permittees by other pre-arranged means.~~

C. Commercial Facilities

~~Within eighteen (18) months of this Order's adoption, the Permittees shall review the E/CS to reflect the following:~~

- ~~1. These Co-Permittees that presently have an existing compliance survey/inspection program for commercial facilities (the cities of Corona and Riverside as to their respective POTW pre treatment inspections and the County through the CAP) shall develop within eighteen (18) months of this Order's adoption, an inventory of the commercial facilities that are surveyed or inspected pursuant to the existing program. The inventory will be updated on a routine basis from such information as conditional use permits, plot plans, building permits, business licenses, occupancy permits, hazardous materials permits, and hazardous waste generator permits are approved for development of a new commercial facility, additional commercial facilities are identified through the CAP and compliance surveys and inspections are completed and new commercial facilities are identified. Each Co-Permittee without a commercial facility inspection program shall include in its inventory of commercial facilities information from the CAP (including automobile mechanical repair, maintenance, fueling, or cleaning; automobile and other vehicle body repair or painting; painting and coating; pool, lake and fountain cleaning (base of operations)) that is relevant to its jurisdiction and may include information derived from other agencies providing services within its jurisdiction, including, but not limited to, the POTW. This inventory shall be maintained in a computer database system. The revised E/CS should provide for the inclusion of the following information: facility name (dba), address, city, zip code, mailing address (if different), location reference (GIS coordinates, cross streets, APN, etc.) facility contact and phone number, SIC code(s), and site size. An electronic copy or update of the database, in a format acceptable to the Executive Officer, shall be provided with each Annual Report or upon request. Linking the database to a GIS is recommended but is not required.~~
- ~~2. In addition, each Permittee shall develop within twenty four (24) months of this Order's adoption, an inventory of the commercial facilities/companies listed below within its jurisdiction:~~
 - ~~a. Mobile automobile or other vehicle washing (base of operations);~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 46 of 4246

- ~~b. Mobile carpet, drape or furniture cleaning (base of operations);~~
 - ~~c. Mobile high pressure or steam cleaning (base of operations);~~
 - ~~d. Nurseries and greenhouses;~~
 - ~~e. Landscape and hardscape installation (base of operations); and,~~
 - ~~f. Other commercial sites/sources that the Permittee determines may contribute a significant pollutant load to the MS4.~~
- ~~3. Within twelve (12) months of this Order's adoption, the CAP will be revised to cause compliance surveys/inspections of restaurants within Riverside County that, at a minimum, include the following:~~
- ~~a. Oil and grease disposal to verify that these wastes are not discharged onto a parking lot, street or adjacent catch basin;~~
 - ~~b. Trash bin areas to verify that these areas are clean, the bin lids are closed, the bins are not filled with liquid, and the bins have not been washed out into the MS4;~~
 - ~~c. Parking lot, alley, sidewalk and street areas to verify that floor mats, filters and garbage containers are not washed in those areas and that no wash water is discharged to MS4s from those areas; and,~~
 - ~~d. Parking lot areas to verify that they are cleaned by sweeping, not by hosing down, and that the facility operator uses dry methods for spill cleanup.~~
- ~~4. The revised E/CS shall prioritize commercial facilities within their jurisdiction as a high, medium, or low threat to water quality. Evaluation of these facilities should be based on such factors as type of commercial activities (SIC codes), materials or wastes used or stored outside, pollutant discharge potential, facility size, proximity and sensitivity of Receiving Waters, frequency of existing inspections, based upon other California statutes or regulations, or local regulations, ordinances, or codes, and any other relevant factors. At a minimum, a high priority classification shall be assigned to facilities with a high potential for or history of unauthorized, non-storm water discharges.~~
- ~~5. Once the inventory required by Subsection C.1, above, has been completed and the commercial facilities have been prioritized, consistent with Subsection C.4, above, the Co-Permittees are to determine the frequency with which the inventoried facilities are surveyed or inspected, pursuant to existing programs. Unless inspected more frequently pursuant to the existing programs, those commercial facilities given a high priority are to be inspected at least once a year, those commercial facilities given a medium priority are to be inspected at least once biannually, and those commercial facilities given a low priority are to be inspected at least once during the term of this Order. In the event that the commercial facility is found to be in violation of the Co-Permittee's Storm Water~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 47 of 4246

~~Ordinances the frequency of inspection shall be increased consistent with a compliance schedule determined appropriate by the Co Permittee and as outlined in the revised E/CS to cause said facility to be brought into compliance.~~

~~6. The commercial facility compliance survey/inspection shall, at a minimum, address the following, consistent with the E/CS:~~

~~a. Commercial activity type(s) and SIC code(s);~~

~~b. Compliance with each Co Permittee's Storm Water Ordinances; If applicable, check for submittal of a NOI to comply with the General Industrial Activities Storm Water Permit or other permit issued by the State or Regional Board; and,~~

~~e. The E/CS.~~

~~7. The Permittees will expand its existing public educational program to include a concentrated, business-specific element. This expanded education element will be described in detail in the WQMP and the DAMP. This education program will include criteria to provide the commercial facility owner and/or operator with information to encourage compliance with the Co Permittees' Storm Water Ordinances and the General Industrial Activities Storm Water Permit or other permit issued by the State or Regional Board, if applicable. If the commercial facility is found to need coverage under the General Industrial Activities Storm Water Permit or other permit issued by the State or Regional Board, information will be provided and the Regional Board will be notified.~~

~~8. Each Co Permittee shall enforce its Storm Water Ordinance prohibiting non-exempt non-storm water discharges at commercial facilities. Sanctions for non-compliance may include: verbal and/or written warnings, notice of violation or non-compliance, obtaining an administrative compliance, stop work, or cease and desist order, a civil citation or injunction, the imposition of monetary penalties or criminal prosecution (infraction or misdemeanor).~~

~~9. The number of compliance surveys/inspections and the actions taken shall be documented by the Co Permittees and an appropriate summary of said actions will be provided to the Principal Permittee for inclusion in the Annual Report submitted to the Regional Board.~~

~~10. Within twenty four (24) hours of receipt of notice by its staff or from a third party, each Co Permittee shall continue to provide oral or e-mail notification to the Regional Board of facilities within its jurisdiction that it perceives to have an illicit connection, illegal discharge, or that is determined to be an Emergency Situation. Following oral or e-mail notification, a written report must be submitted to Regional Board Staff within ten (10) calendar days of the Co-Permittee's receipt of notice of the Emergency Situation. All written reports shall detail the nature of the Emergency Situation, identify corrective actions taken by the facility owner, and note other relevant information (e.g., past~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 48 of 4246

~~history of non-compliance, environmental damage resulting from the Emergency Situation, facility owner or manager's responsiveness) and the type of enforcement, consistent with Table 4 of the E/CS, that has been or will be carried out by the Co-Permittee. Further, incidences of non-compliance shall be recorded along with the information noted in the written report and the final outcome/enforcement for the incident will be included in the database identified in Subsection C.1, above.~~

~~11. If a Co-Permittee discovers, or receives notice by its staff or from a third party of a non-Emergency Situation representing a possible violation of the General Industrial Activity Storm Water Permit, if applicable to the commercial facility, or other permit issued by the State or Regional Board to a commercial facility, the Co-Permittee shall, within two (2) working days, provide written notice to Regional Board staff of the location within its jurisdiction where the incident occurred and describing the nature of the incident.~~

~~12. Not all commercial facilities are required to obtain coverage under the General Industrial Activities Storm Water Permit. However, if required to obtain coverage and upon referral of a commercial facility to Regional Board staff for failure to obtain coverage under the General Industrial Activities Storm Water Permit, failure to keep a SWPPP at the commercial facility, or an observed act or omission that suggests failure to comply with the General Industrial Activities Storm Water Permit, the Co-Permittee will take no further action at the commercial facility with regard to securing compliance with the General Industrial Activities Storm Water Permit. It is understood by the Co-Permittees and Regional Board staff that this will preclude duplication of effort and insure that consistent direction is provided to the facility owner/manager as to what is required to bring the facility into compliance with the General Industrial Activities Storm Water Permit. Each Co-Permittee shall take appropriate actions to bring a commercial facility into compliance with its local ordinances, rules, regulations, and WQMP, when approved.~~

~~13. As described in the E/CS, Co-Permittees will provide training to staff that is involved in the compliance surveys/inspections of commercial facilities. Staff training will address the requirements of the following:~~

~~a. The Storm Water Ordinance;~~

~~b. This Order and the DAMP;~~

~~c. The General Industrial Activities Storm Water Permits and any other permit issued to a commercial facility within the Permit Area by the State or Regional Board;~~

~~d. The E/CS;~~

~~e. Pollution prevention plans; and,~~

~~f. Implementation and maintenance of appropriate BMPs for commercial sites.~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 49 of 4246

~~14. Training programs should be coordinated with Regional Board staff and prior notification of formal classroom training activities shall be provided to Regional Board staff.~~

~~15. Each Co-Permittee shall have arranged for adequate training of its current municipal staff assigned to conduct the commercial facility compliance survey/inspection within eighteen (18) months of this Order's adoption, and on an annual basis thereafter. New hires or transfers that will be performing the commercial facilities compliance surveys/inspections for a Co-Permittees will be trained within six (6) months of starting field duties.~~

X. TOTAL MAXIMUM DAILY LOADS

- A. Nutrient TMDLs for Lake Elsinore and Canyon Lake and Pathogen Indicator TMDLs for the Middle Santa Ana River have been incorporated into Chapter 5 of the Basin Plan. These TMDLs include WLA and Implementation Plan Tasks assigned to specific Permittees. Those Permittees shall comply with the TMDLs WLA by complying with the TMDL Implementation Plan task requirements as described in Chapter 5 of the Basin Plan. Section 13 of the DAMP shall describe the TMDL Implementation Plan tasks.
- B. The Permittees shall modify sSection 13 of the DAMP, as necessary, to incorporate appropriate BMPs to address future USEPA approved TMDL WLA per the requirements of the associated TMDL Implementation Plan tasks assigned to the Permittees. Revisions to the DAMP shall be implemented in accordance with the Implementation Plan for the TMDL WLA.
- C. As Part of the Permittees next ROWD, the Permittees shall evaluate their compliance with the adopted TMDLs and TMDL Implementation Plan tasks referenced in sSection X.A, and propose any new or modified BMPs necessary to achieve compliance with the Permittees' TMDL WLA by the dates specified in the respective TMDL Implementation Plans in Chapter 5 of the Basin Plan.

XI. PUBLIC EDUCATION AND OUTREACH

- A. ~~The storm waterUrban Runoff regulations require public participation in the Urban Runoff management program development and implementation. As such the Permittees shall solicit and consider comments received from the public and submit copies of the comments to the Executive Officer with the Annual Reports due on November 30th, beginning with the report due on November 30, 2003. In response to the public comments, the Permittees may modify reports, plans, or schedules prior to submittal to the Executive Officer.~~
- B. ~~The Permittees shall continue to participate in a joint outreach with other programs including, but not limited to, the California Urban Runoff Quality Task Force, Caltrans, and other Urban Runoff programs to disseminate a consistent message on Urban Runoff pPollution pPrevention to the public. The Permittees shall continue to sponsor or staff an Urban Runoff table or booth at community, regional, and/or countywide~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 50 of 4246

events to distribute public education materials to the public. Each Permittee shall sponsor at least one event per year that provides a venue for Urban Runoff education outreach.

~~C. Within six (6) months of this Order's adoption, t~~The Permittees shall maintain establish a Public Education Committee to provide oversight and guidance for the implementation of the public education program. The ~~Public Education Committee shall meet at least twice per year. The Public Education Committee shall make recommendations for changes to the public and business education program. The goal of the public and business education program shall be to target 100% within the Permit Area of the residents, including businesses, commercial and industrial establishments and to measurably increase the awareness of Urban Runoff quality of the targeted groups. Through use of local print, radio and television, t~~The Permittees must ensure that the public and business education program makes a minimum of 5 million "impressions" per year (as defined in Appendix 4, Glossary).

~~D. Within twelve (12) months of formation, the Public Education Committee shall conduct an evaluation to determine the best method of establishing a procedure(s) for providing educational and General Industrial Activities Storm Water Permit compliance guidance materials to businesses within their jurisdiction. This procedure(s) for distributing educational materials to businesses shall be implemented within six (6) months after conducting said evaluation.~~

D. The Permittees shall continue to implement the public education efforts already underway and shall modify the program as necessary to promote implement the most effective elements of the public and business education strategy contained in the Only Rain Down the Storm Drain Storm Water/Clean Water Protection Program. Within eighteen (18) months of formation, the Public Education Committee shall propose a survey for measuring changes in awareness of Urban Runoff quality as a result of the education program. The findings of this survey will provide information for the development of a future Public Education action plan. Upon approval by the Executive Officer, the study shall be completed by the end of the permit cycle.

~~F. Within twelve (12) months of this Order's adoption, the Public Education Committee shall develop BMP guidance for restaurants, automotive service centers, and gasoline service stations, and the discharges listed in Section II.C.IX.C.2. of this Order, where appropriate, for the Co-Permittees to distribute to these facilities.~~

E. The Permittees will continue to implement the concentrated, business-specific element of the existing public educational program as described in sSection 10 of the DAMP.

F. Within twelve (12) months of this Order's adoption, tThe Permittees shall distribute develop public education materials to encourage the public to report (including a hotline line number to report) illegal dumping from residential, industrial, construction and commercial sites into public streets, storm drains and other waterbodies, clogged storm drains, and faded or missing catch basin stencils, and In addition, Permittee websites and hotlines should provide access to information regarding general Urban Runoff and BMP information. This Principal Permittee's hotline and website shall continue to be included in the public and business education program and shall be submitted for listing in the governmental pages of all major regional phone books.

G. ~~Within eighteen (18) months of this Order's adoption, t~~The Permittees shall continue to distribute~~develop~~ BMP guidance for the household use of fertilizers, pesticides, and other chemicals, mobile vehicle maintenance, carpet cleaners, residential, business and construction activities found to be a significant source of Pollutant~~se~~commercial landscape maintenance, and pavement cutting. Additionally, BMP guidance shall be developed for categories of discharges listed in Section II.C, identified to be significant sources of pollutants unless appropriate BMPs are implemented. These guidance documents shall continue to be distributed to the public, trade associations, etc., through participation in community events, trade association meetings, and/or mail.

XII. PERMITTEEMUNICIPAL FACILITIES PROGRAMS AND ACTIVITIES

A.B. Successful implementation of the provisions and limitations in this Order will require the cooperation of all the public agency organizations within Riverside County having programs/activities that have an impact on Urban Runoff quality. This may include, but not be limited to, those listed in Appendix 2. As such, the Regional Board will coordinate with these organizations to ensure participation~~are expected to actively participate~~ in implementing this area-wide Urban Runoff program. The Permittees shall notify the Regional Board of non-compliance. The Permittees shall be responsible for involving the public agency organizations in their Urban Runoff program.

G. ~~Within eighteen (18) months of this Order's adoption, the Permittees, in coordination with the Riverside County Fire Chiefs Association, or equivalent organization, shall develop a list of appropriate BMPs to be implemented to reduce pollutants from fire training activities, fire hydrant/sprinkler testing or flushing, and BMPs feasible for emergency fire fighting flows.~~

C. Each Permittee shall continue to implement measures ~~the recommendations in the Municipal Facilities Strategy to ensure that their public agency facilities and activities do not cause or contribute to a pPollution or aNuisance in Receiving Waters, as defined in Section 13050 of the Water Code. By August 1 of each year, the Permittees shall review their activities and facilities to determine the need for revisions to sSection 5 of the DAMPMunicipal Facilities Strategy. The Annual Report shall include the findings of this review and a schedule for needed revisions. Revisions should consider a pPollution pPrevention strategy to ensure that the public agency facilities and/or activities including those that are currently not required to obtain coverage under the Storm Water State's General Permits Urban Runoff Permits or the San Jacinto Watershed Construction Activities Permit are not sources of pPollutants into the Waters of the U.-S.- In addition, the Permittees shall evaluate the applicability of the DAMPMunicipal Facilities Strategy to Permitteemunicipal maintenance contracts, contracts for field maintenance operations, and leases.~~

I. ~~Within six (6) months of adoption of this Order, the Permittees shall evaluate their established criteria for inspections of the MS4s and establish criteria for regular maintenance thereof.~~

J. ~~Within twenty (20) months of this Order's adoption, the Permittees shall complete an assessment of their MS4s to evaluate opportunities to configure and/or to reconfigure~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 52 of 4246

~~channel segments to function as pollution control devices and to optimize beneficial uses. These modifications may include in-channel sediment basins, bank stabilization, water treatment wetlands, etc. This shall be reported in the 2004-2005 Annual Report.~~

- ~~K. Within twelve (12) months of this Order's adoption, the Permittees shall develop and distribute model maintenance procedures for public agency activities and MS4s such as street sweeping, catch basin stenciling, MS4 inspection, "cleaning" (see definition in Appendix 4), and maintenance. This shall be included in the 2004-2005 Annual Report.~~
- ~~D. Within twelve (12) months of this Order's adoption, ~~t~~The Permittees shall implement the review, document, and submit for approval by the Executive Officer, their program for cleaning out open channel MS4s, catch basins, retention/detention basins, and wetlands created for Urban Runoff treatment, prioritized on such factors as distance to Receiving Water, Receiving Water beneficial uses and impairments of beneficial uses, historical pollutant types and loads from past inspections/cleanings, regulatory restrictions, cost/benefit, and the presence of downstream regional facilities that would remove the types of pollutants found in the drainage facilities. Using these factors, the Permittees shall propose revised clean out schedules and frequency for the specified MS4 facilities as described in the 2003-2004 Annual Report during the wet and dry season to protect Receiving Water quality to the MEP. The Permittees should be prepared to implement the approved clean out program within twenty four (24) months of this Order's adoption. The inspection and cleaning maintenance frequency for all portions of the MS4s described in the 2003-2004 Annual Report shall be included in each Permittee's LIP and shall be observed/evaluated annually to determine the need for increasing the inspection and cleaning maintenance frequency and This information shall initially be included in the 2003-2004-2012 ROWD Annual Report. Each Permittee shall clean those MS4 facilities where there is evidence of Illegal Discharge. In addition, each Permittee shall clean those retention/detention basins where the inspection reveals that the storage volume is about 25% full or if accumulated Sediment or debris impairs the hydraulic capacity of the facility.~~
- ~~M. If by November 1, 2004, the Permittees have not developed revised clean out schedules and frequencies, required in Subsection G, above, and/or the revised schedules and frequencies have not been approved by the Executive Officer, then each Permittee shall expand existing programs to inspect, clean, and maintain at least 80% of its open channel MS4s, catch basins, retention/detention basins, and wetlands created for Urban Runoff treatment on an annual basis, with 100% of the facilities included in a two year period, using the model maintenance procedures developed by the Permittees in Subsection F, above. Each Permittee shall clean those open channel MS4s and retention/detention basins where there is evidence of illegal discharge. In addition, each Permittee shall clean those retention/detention basins where the inspection reveals that the sediment/storage volume is about 25% full or if accumulated sediment or debris impairs the hydraulic capacity of the facility.~~

Contractor training requirements for Urban Runoff management shall be included in new contracts and contracts that come up for renewal. This shall be reported in the 2002-2003 Annual Report.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 53 of 4246

- ~~E. Within eighteen (18) months of this Order's adoption, t[he Principal Permittee shall continue to develop and distribute BMP guidance for public agency and contract field operations and maintenance staff to provide guidance in appropriate p[re]vention control measures, how to respond to spills and reports of i[ll]legal d[is]charges, etc. This shall be reported in the 2004-2005 Annual Report.~~
- ~~P. At least on an annual basis, each Permittee shall provide training to the public agency staff and to contract field operations staff on fertilizer and pesticide management, model maintenance procedures, and other pollution control measures. Permittee staff responsible for application of fertilizer or pesticides shall attend at least three of these training sessions during the five-year term of this Order (from 2002 to 2007).~~
- ~~Q. Each Permittee shall identify areas that are not subject to street sweeping due to lack of continuous curb and gutter, and evaluate their potential for impacting Urban Runoff quality. Appropriate BMPs shall be implemented where significant water quality impact is identified associated with lack of street sweeping. This shall be reported in the 2003-2004 Annual Report.~~
- ~~R. Each Permittee shall annually evaluate their street/road sweeping frequency based on land use and historical information to determine the need to revise their sweeping frequency. This information shall be provided in the Annual Report beginning with the 2003-2004 Annual Report.~~
- ~~F. The Permittees shall maintain an updated site-specific Urban Runoff p[re]vention p[lan] for their facilities and activities with potential to contribute to Pollution or Nuisance in Receiving Waters.~~

~~The San Bernardino County Flood Control District and RCFC&WCD, in cooperation with local municipalities, are coordinating an effort to construct flood control facilities in the Chino-Corona Agricultural Preserve area. A status report of this project shall be provided in the Annual Report.~~

XIII. PERMITTEEMUNICIPAL COMPLIANCE WITH GENERAL PERMITSCONSTRUCTION PROJECTS/ACTIVITIES

A. Permittee Compliance with the General Permit-Construction

- ~~1. All Permitteemunicipal construction activity shall be in compliance with the latest version of the applicable General Permit-Construction-Activity Permit.~~
- ~~2. This Order authorizes the discharge of storm water runoff from construction projects that may result in "land disturbance" (as defined in Appendix 4, Glossary) consistent with the acreage criteria of the current-latest version of the General Permit-Construction-Activity Storm Water Permit.~~
- ~~3. By March 10, 2003, or as specified in the latest version of the General Construction Activity Storm Water Permit, t[he Permittees shall comply with the requirements for theirmunicipal construction projects that may result in l[and] d[isturbance]~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 54 of 4246

consistent with the acreage criteria of the latest version of the current General Permit-Construction Activity Permits.

4. Prior to commencement of construction activities, the Permittees shall notify the Executive Officer of the proposed construction project by submitting a ~~Notice of Intent (NOI)~~ as provided in Attachment 5. The submittal fees for these NOIs are waived for the Permittees. Upon completion of the construction project, the Executive Officer shall be notified of the completion of the project by submitting a Notice of Termination (NOT), provided in Attachment 5.
5. The Permittees shall develop and implement a SWPPP and a monitoring and reporting program that is specific for the construction project prior to the commencement of construction activities. The SWPPP shall be kept at the construction site and released to the public and/or Regional Board staff upon request.
6. The SWPPP and the monitoring and reporting program for the construction projects shall be consistent with the requirements of the latest version of the General Permit-Construction Activity Permits, as applicable for the size and location of the site. ~~If the site is within the San Jacinto Watershed then the terms and conditions of the San Jacinto Watershed Construction Activities Permit apply, except with respect to submittal of a fee with the NOI and the requirement for this Regional Board to review and approve the site specific SWPPP. The applicable Permittee shall review and approve the SWPPP prepared by their contractor to insure the SWPPP substantially complies with the San Jacinto Watershed General Permit-Construction Activities Permit. Upon request, the applicable Permittee shall submit a copy of the approved SWPPP to the Regional Board.~~
7. The Permittees shall give advance notice to the Executive Officer of planned changes in the construction activity, which may result in non-compliance with the latest version of the General Permit-Construction Activity Permits, as applicable.
8. Emergency Permittee public works projects required to protect public health and safety are exempted from compliance with the ~~SWPPP~~ requirements of ~~Subsections E, and the requirements of subsections F and G XIII.A.6, XIII.A.7, and XIII.A.8, above.~~

B. Permittee Compliance with the General Permit-De Minimus Discharges

Permittees owning potable water supply system(s), when performing maintenance on the system(s), shall follow provisions outlined in the General Permit-De Minimus Discharges. Other Permittee activities that would fall under the General Permit-De Minimus Discharges include hydrant flushing and construction dewatering activities. Section 5 of the DAMP incorporates minimum BMPs necessary to ensure compliance with Order R8-2003-0061, so separate coverage under that permit is not required.

C. Permittee Compliance with the General Permit-Utility Vaults

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 55 of 4246

The General Permit-Utility Vaults covers short-term intermittent discharges from utility vaults and underground structures to Waters of the U.S. that do not cause, have the reasonable potential to cause, or contribute to an instream excursion above any applicable state or federal Water Quality Objectives/Criteria or cause acute or chronic toxicity in Receiving Waters. Section 5 of the DAMP (Permittee Facilities and Activities) incorporates minimum BMPs necessary to ensure compliance with the General Permit-Utility Vaults, so separate coverage under that permit is not required.

D. Permittee Compliance with the General Permit-Small Linear Underground Projects

The General Permit-Small Linear Underground Projects covers discharges of stormwater runoff associated with small linear underground/overhead construction projects. Section 5 of the DAMP (Permittee Facilities and Activities) incorporates minimum BMPs necessary to ensure compliance with the General Permit-Small Linear Underground Projects, so separate coverage under that permit is not required.

XIV. TRAINING OF PERMITTEE STAFF

- A. Each Permittee's LIP shall describe a program to provide formal and informal training to Permittee staff that implements the provisions of this Order (i.e. construction site inspectors, industrial/commercial facility inspectors, municipal maintenance employees, municipal development review employees, etc).
- B. Formal (classroom or computer based) Training Programs must address the following:
1. The requirements of Storm Water Ordinances, resolutions, and codes that relate to the duties of the target audience;
 2. The provisions of this Order that relate to the duties of the target audience;
 3. The provisions of the General Permit-Construction, the General Permit-Industrial, and any other permit issued within the Permit Area by the State or Regional Board that is appropriate due to the relationship of the permit provisions to the duties of the target audience;
 4. Implementation and assessment of appropriate Pollution Prevention Plans relative to the duties of the target audience;
 5. Selection, implementation and maintenance of appropriate BMPs relative to the duties of the target audience;
- C. At a minimum, the Permittees shall jointly, or individually, develop, implement and document formal training programs that target Permittee construction inspectors, Permittee industrial and/or commercial facility inspectors, Permittee maintenance employees and Permittee development review staff. Formal training should be summarized and documented in the Annual Reports. Training schedule shall be as follows:

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 56 of 4246

1. New probationary employees responsible for implementing requirements of this Order shall receive formal training within six months of hire.
 2. Existing career employees shall receive follow-up formal training at least once during the Permit term.
 3. Construction and stormwater inspection employees shall receive refresher training focused on appropriate BMP implementation at least once a year prior to the rainy season.
- D. Formal training programs should be coordinated with Regional Board staff and prior notification of formal classroom training activities shall be provided to Regional Board staff.
- E. The Permittees shall jointly or individually provide for annual informal training programs that address the topics discussed in sSection XIV.B. Informal training programs may include training that occurs during Permittee staff meetings, tailgate field trainings, supervisor procedure reviews with Permittee employees or similar informal activities. Formal training may be substituted for informal training. Informal training activities shall be documented.

XV. PROGRAM MANAGEMENT/DAMP REVIEW

- A. The Permittees shall continue to implement all elements of the approved DAMP. Program elements revised in compliance with the requirements of this Order shall be implemented in conformance with the schedules specified in this Order following approval of the Executive Officer. ~~Within six (6) months of approval of the WQMP by the Executive Officer, or no later than January 1, 2005, whichever comes first, the Permittees shall submit a revised DAMP incorporating the revised program elements and other information as specified by this Order for approval by the Executive Officer. The Permittees shall implement all elements of the approved DAMP.~~
- B. ~~By August 1 of each year, beginning in 2004,~~ the Permittees shall evaluate the effectiveness of the Urban Runoff management program described in the DAMP ~~to determine the need for revisions.~~ The Permittees shall modify the DAMP, as necessary, or at the direction of the Executive Officer to incorporate additional provisions to improve the effectiveness of the Urban Runoff management program. Such provisions may include regional and watershed-specific requirements and/or WLAs developed and approved pursuant to the TMDL process for Impaired Waterbodies. Proposed revisions to the DAMP shall be submitted to the Executive Officer for review and approval. Revisions to the DAMP approved by the Executive Officer shall be implemented in a timely manner. The Annual Report shall include the findings of this review and a schedule for needed revisions.

C. At a minimum, each Annual Report shall include a progress report of:

~~1. The formal training and coordination meeting needs for the Co-Permittees' staff responsible for performing compliance survey/inspections or educational programs;~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 57 of 4246

~~2. Source identification and prioritization;~~

~~3. Grading and erosion control for construction sites;~~

~~4. Verification of coverage under the appropriate General Construction and Industrial Activities Permits;~~

~~5. Facility inspection and enforcement consistent with local ordinances, rules, and regulations;~~

~~6. Procedures for reporting to the Permittees and this Regional Board non-compliance with each Co-Permittee's Storm Water Ordinance and enhancing current planning review processes to better address issues regarding Urban Runoff;~~

~~7. Implementation of new development BMPs, or identification of regional or sub-regional Urban Runoff treatment/infiltration BMPs in which New Development projects could participate.~~

- C. Each Permittee shall designate at least one representative to the Management Steering Committee and Technical Committee as described in Sections I.A.2.a and II.B.2.a of this Order. The Principal Permittee shall be notified immediately, in writing of changes to the designated representative to either Committee. The designated representative for each Committee shall attend that Committee's meeting as follows: at least three (3) out of four (4) Management Steering Committee meetings and eight (8) out of ten (10) Technical Committee meetings per year.

XVI. MONITORING AND REPORTING PROGRAM

The Permittees shall comply with Monitoring and Reporting Program No. ~~R8-2002-0044~~R8-2007-xxxx, located in Appendix 3, and any revisions thereto, which are hereby made a part of this Order. The Executive Officer is hereby authorized to revise the Monitoring and Reporting Program in a manner consistent with this Order to allow the Permittees to participate in regional, statewide, national or other monitoring and reporting programs in lieu of or in addition to Monitoring and Reporting Program No. ~~R8-2002-0044~~R8-2007-xxxx located in Appendix 3. In addition, significant completion and implementation dates required by this Order are outlined in Section V of the Monitoring and Reporting Program (~~Appendix 3~~).

XVII. PROVISIONS

A. GENERAL

1. Reports submitted by the Permittees as per the requirements in this Order for the approval of the Executive Officer shall be publicly noticed and made available on the Regional Board's website, or through other means, for public review and comments. The Executive Officer shall consider all comments received prior to approval of the reports. Unresolved issues shall be scheduled for a public hearing at a Regional Board meeting prior to approval by the Executive Officer.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 58 of 4246

2. The purpose of this Order is to require the implementation of BMPs to reduce, to the MEP, the discharge of ~~p~~Pollutants from ~~the MS4s~~ in order to support further progress towards attainment of ~~w~~Water ~~q~~Quality ~~e~~Objectives.
3. Permittees shall demonstrate compliance with all the requirements in this Order and shall implement their DAMP and modifications, revisions, or amendments thereto, which are developed pursuant to this Order or determined by the Permittees to be necessary to meet the requirements of this Order and approved by the Executive Officer. The DAMP and amendments thereto are hereby made an enforceable part of this Order.
4. Each Permittee shall continue to implement necessary controls, in addition to those specific controls and actions required by (1) the terms of this Order and (2) the DAMP, to reduce the discharge of ~~p~~Pollutants in Urban Runoff to the MEP.
5. The Permittees shall complete changes to plans or programs described in this Order no later than twelve (12) months after this Order goes into effect, unless otherwise specified.
6. Certain BMPs implemented or required by the Permittees for Urban Runoff management may create habitat for vectors (e.g., mosquitoes and rodents) if not properly designed and maintained. Close collaboration and cooperative effort between the Permittees and local vector control agencies and the State Department of Health Services during the development and implementation of Urban Runoff management programs are necessary to minimize potential vector habitat and public health impacts resulting from vector breeding. Nothing in this Order is intended to prohibit inspection or abatement of vectors by the State or local vector control agencies in accordance with the Health and Safety Code of the State of California.
7. The Permittees shall report to the Executive Officer:
 - a. Any enforcement actions and known discharges of Urban Runoff or wastewater to MS4 facilities owned or operated by the Permittees which may impair domestic water supply sources (e.g., discharges due to a levee break, ~~i~~llegal ~~e~~Discharges to the street, etc.) or which may have an impact on human health or the environment; if the discharge is to Canyon Lake or any tributary to Canyon Lake, Elsinore Valley Municipal Water District shall also be notified immediately;
 - b. Industrial and/or construction facilities found not to be in compliance with the Storm Water General Construction Activity Permits, or where the activities may be contributing ~~p~~Pollutants to the Waters of the U.-S.; and,
 - c. Suspected or reported activities on federal, state, or other entity's land or facilities, where the Permittees do not have any jurisdiction, and where the suspected or reported activities may be contributing ~~p~~Pollutants to the Waters of the U.-S.

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 59 of 4246

8. The Permittees shall coordinate their activities to promote consistent implementation of storm water ~~Urban Runoff~~ regulations.
9. The Permittees must comply with all terms, requirements, and conditions of this Order. Any violation of this Order constitutes a violation of the CWA, its regulations and the Water Code, and is grounds for enforcement action, Order termination, Order revocation and re-issuance, denial of an application for re-issuance, Order revisions, or a combination thereof.
10. Permittees shall continue to take reasonable steps to minimize or prevent any discharge to the MS4 that has a reasonable likelihood of adversely affecting human health or the environment.
11. Regional Board staff, USEPA, and other authorized representatives shall be allowed to:
 - a. Inspect Permittee records associated with compliance of this Order.
 - b. Access to and copying of records that are kept under the conditions of this Order.
 - c. Photograph and inspect any facilities or equipment (including monitoring and control equipment) that are related to or may impact storm water discharge or authorized ~~Non-storm w~~ Water discharge.
 - d. Conduct sampling, and monitoring activities for the purpose of assuring compliance with this Order, or as otherwise authorized by the CWA and/or the Water Code.
 - e. Review the Permittee's programs and require modification to their programs to comply with the requirements of this Order.
 - f. Request copies of data, monitoring reports, and sampling data and copies of the Permittee's conclusions and evaluations of the data.

B. FISCAL RESOURCES

—The Permittees shall prepare and submit a unified fiscal analysis report appropriate for implementation of the requirements of this Order to the Executive Officer. ~~The fiscal analysis report shall be submitted no later than November 30, of each year and shall at a minimum include the following:~~

—
~~Each Permittee's expenditures for the previous fiscal year;~~

~~Each Permittee's budget for the current fiscal year;~~

~~A description of the source of funds;~~

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 60 of 4246

XVIII. PERMIT EXPIRATION AND RENEWAL

A. This Order expires on ~~October 26~~ August XX, 2012~~07~~, and the Permittees must file a ROWD no later than one hundred eighty (180) calendar days in advance of such expiration date as application for issuance of new Waste Discharge Requirements. The ROWD shall, at a minimum, include the following:

1. Any revisions to the DAMP including, but not limited to, activities the Permittees propose to undertake during the next permit term, goals and objectives of such activities, an evaluation of the need for additional Treatment~~source~~ Control and/or structural BMPs, proposed pilot studies, etc.;
2. Any new or revised program elements and compliance schedule(s) necessary to comply with Section III of this Order;
- ~~2-3.~~ Changes in land use and/or population including map updates; and
4. Significant changes to the MS4s, outfalls, detention or retention basins or dams, and other controls, including map updates of the MS4s.

B. This Order may be modified, revoked or reissued prior to its expiration date for the following reasons:

1. To address significant changes in conditions identified in the technical reports required by the Regional Board which were unknown at the time of the issuance of this Order;
2. To incorporate applicable requirements of statewide water quality control plans and policies adopted by the State Board or amendments to the Basin Plan approved by the Regional Board, the State Board, and, if necessary, by the Office of Administrative Law; or
3. To comply with applicable requirements, guidelines, or regulations issued or approved under the CWA, if the requirements, guidelines, or regulations contain different conditions or additional requirements than those included in this Order.
4. To incorporate new or revised program elements and compliance schedule(s) necessary to comply with this Order.
5. To incorporate any requirements imposed upon the Permittees through the TMDL process.
6. Pursuant to Section 13228 of the Water Code, ~~this~~ Regional Board may exercise its option allowing the portion of recently annexed 375 acres to the City of Murrieta that are located within the Region to be regulated by the San Diego Regional Water Quality Control Board's Riverside MS4 Permit once it has been renewed.

C. This Order shall serve as a NPDES permit pursuant to Section 402-(p) of the CWA, or amendments thereto, and shall become effective ten (10) calendar days after the date

Order No. R8-2007-xxxx (NPDES No. CAS 618033)
Area-wide Urban Runoff
RCFC&WCD, the County of Riverside, and the Incorporated Cities

Page 61 of 4246

of its adoption provided the Regional Administrator of the USEPA has no objections. If the Regional Administrator objects to its issuance, this Order shall not become effective until such objection is withdrawn.

D. Order No. ~~96-30~~R8-2002-0011 is hereby rescinded.

I, Gerard J. Thibeault, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of an Order adopted by the California Regional Water Quality Control Board, Santa Ana Region, on October 25, 2002.

Gerard J. Thibeault
Executive Officer

April 27, 2007

ATTACHMENT 48

**California Regional Water Quality Control Board
Santa Ana Region**

RESOLUTION NO. R8-2005-0001

**Resolution Amending the Water Quality Control Plan for the Santa Ana River Basin to
Incorporate Bacterial Indicator Total Maximum Daily Loads (TMDLs) for Middle Santa Ana
River Watershed Waterbodies**

WHEREAS, the California Regional Water Quality Control Board, Santa Ana Region (hereinafter, Regional Board), finds that:

1. An updated Water Quality Control Plan for the Santa Ana River Basin (Basin Plan) was adopted by the Regional Board on March 11, 1994, approved by the State Water Resources Control Board (SWRCB) on July 21, 1994, and approved by the Office of Administrative Law (OAL) on January 24, 1995.
2. The waterbodies within the Middle Santa Ana River Watershed listed on the Clean Water Act Section 303(d) list for bacterial contamination are as follows: Santa Ana River, Reach 3; Chino Creek, Reach 1; Chino Creek, Reach 2; Mill Creek (Prado Area); Cucamonga Creek, Reach 1; and Prado Park Lake.
3. Water contact recreation (REC1) and non water contact recreation (REC2) are among the beneficial uses designated in the Basin Plan for the Santa Ana River, Reach 3, Chino Creek, Reaches 1 and 2, Mill Creek (Prado Area), Cucamonga Creek, Reach 1, and Prado Park Lake.
4. For the protection of REC1 beneficial uses of inland surface waters, including the Middle Santa Ana River Watershed Waterbodies, the Basin Plan specifies the following numeric water quality objectives for fecal coliform indicator bacteria: log mean less than 200 organisms/100 mL based on five or more samples per 30 day period, and not more than 10% of the samples exceed 400 organisms/100 mL for any 30-day period.
5. The numeric fecal coliform water quality objectives are not being met in Middle Santa Ana River Watershed Waterbodies. The beneficial use adversely affected by elevated fecal coliform densities in Middle Santa Ana River Watershed Waterbodies is REC1.
6. As a result of violations of the fecal coliform objectives and beneficial use impacts to the Middle Santa Ana River waterbodies, the Regional Board listed these waterbodies as water quality limited in accordance with Section 303(d) of the Clean Water Act. Section 303(d) requires the establishment of a Total Maximum Daily Load (TMDL) for the pollutant(s) causing surface water impairment. The purpose of the TMDL is to assure that water quality standards are achieved. TMDLs to address fecal coliform impairment of the Middle Santa Ana River Watershed Waterbodies are required. Section 303(d) also requires the allocation of each TMDL among the sources of fecal coliform inputs. State law requires an implementation plan and schedule to ensure that the TMDL is met.
7. The TMDLs/Basin Plan amendment shown in the attachment to this Resolution was developed in accordance with Clean Water Act Section 303(d) and Water Code Section 13240 *et seq.* The TMDLs/Basin Plan amendment include background information concerning the water quality impairment being addressed, and the sources of fecal coliform to Middle Santa Ana River

waterbodies. The proposed TMDLs are supported by a detailed report prepared by Regional Board staff and titled "Total Maximum Daily Loads for Bacterial Indicators in the Middle Santa Ana River Watershed", February 3, 2005.

8. The TMDLs/ Basin Plan amendment will be incorporated into Chapter 5 "Implementation", of the Basin Plan.
9. The TMDLs/Basin Plan amendment specifies numeric targets for fecal coliform to be achieved in all Middle Santa Ana River Waterbodies. Control of fecal coliform is needed to ensure compliance with relevant numeric water quality objectives specified in the Basin Plan.
10. The U.S. Environmental Protection Agency (USEPA) has required the states to evaluate and incorporate more appropriate bacterial indicators, including *Escherichia coliform (E. coli)* as water quality standards based on its "Ambient Water Quality Criteria for Bacteria – 1986". The TMDLs/Basin Plan amendment specify alternative numeric targets for *E. coli* to be achieved in all Middle Santa Ana River Waterbodies. The *E. coli* targets are based on USEPA *E. coli* criteria that roughly correspond to the health risk level associated with the existing Basin Plan fecal coliform objectives.
11. The TMDLs/Basin Plan amendment specify Dry Season TMDLs, wasteload allocations for point source discharges (WLAs) and load allocations for nonpoint source discharges (LAs) for fecal coliform and *E. coli* in Middle Santa Ana River Watershed waterbodies. Compliance with the Dry Season TMDLs, wasteload allocations and load allocations is to be achieved as soon as possible, but no later than December 31, 2015.
12. In recognition of the difficulties associated with the control of stormwater discharges, the TMDLs/Basin Plan amendment specify Wet Season TMDLs, waste load allocations for point source discharges and load allocations for nonpoint source discharges for fecal coliform and *E. coli* in Middle Santa Ana River Watershed waterbodies. Compliance with the Wet Season TMDLs, waste load allocations and load allocations is to be achieved as soon as possible, but no later than December 31, 2025.
13. To account for unknowns such as bacterial re-growth, die-off and dilution, the TMDLs/Basin Plan amendment specify an explicit margin of safety of 10% applied to the TMDLs, waste load allocations and load allocations.
14. The TMDLs/Basin Plan amendment specify an implementation plan for bacteria reduction. The implementation plan includes compliance schedules for achieving the numeric targets, TMDLs, wasteload allocations and load allocations, as well as a monitoring program to track progress toward compliance.
15. Stakeholders throughout the Santa Ana Region have formed the Storm Water Quality Standards Task Force (SWQSTF) to evaluate USEPA's bacterial indicator recommendations and appropriate recreational beneficial use designations for waterbodies throughout the Region. The SWQSTF is expected to make recommendations for the adoption of alternative bacterial quality indicators such as *E. coli*, based on USEPA's "Ambient Water Quality Criteria for Bacteria – 1986". These and other recommendations of the SWQSTF for revisions to recreational beneficial use designations will be considered through the Basin Planning process. When and if the Basin Plan is amended to incorporate new bacterial indicators, these TMDLs will be revised as appropriate.

16. The TMDLs/Basin Plan amendment will assure the reasonable protection of the beneficial uses of surface waters within the Region and is consistent with the state's antidegradation policy (SWRCB Resolution No. 68-16).
17. The Regional Board has considered the costs associated with implementation of this amendment, as well as costs resulting from failure to implement bacteria control measures necessary to prevent adverse effects on beneficial uses. The implementation plan in the TMDLs/Basin Plan amendment, which includes extended compliance schedules and employs a phased TMDL approach to provide for refinement based on additional studies and analyses, will ensure that implementation expenditures are reasonable and fairly apportioned among responsible parties.
18. The proposed amendment results in no potential for adverse effects, either individually or cumulatively, on fish and/or wildlife species.
19. The adoption of these TMDLs is necessary to reduce loadings of fecal coliform to Middle Santa Ana River waterbodies and to address water quality impairments that arise therefrom.
20. The proposed amendment meets the "Necessity" standard of the Administrative Procedure Act, Government Code, Section 11352, subdivision (b).
21. The Regional Board submitted the relevant technical documents that serve as the basis for the proposed amendment to an external scientific peer reviewer and has considered the comments and recommendations of the peer reviewer in drafting the amendment. The peer reviewer found the TMDLs to be scientifically valid.
22. The Regional Board discussed this matter at workshops conducted on February 3, 2005 and June 24, 2005 after notice was given to all interested persons in accordance with Section 13244 of the California Water Code. Based on the discussion at these workshops, the Board directed staff to prepare the appropriate Basin Plan amendment and related documentation to incorporate the Middle Santa Ana River Bacterial Indicator TMDLs.
23. The Regional Board prepared and distributed written reports (staff reports) regarding adoption of the TMDLs/Basin Plan amendment in accordance with applicable state and federal environmental regulations (California Code of Regulations, Section 3775, Title 23, and 40 CFR Parts 25 and 131).
24. The process of basin planning has been certified by the Secretary for Resources as exempt from the requirement of the California Environmental Quality Act (Public Resources Code Section 21000 et seq.) to prepare an Environmental Impact Report or Negative Declaration. The TMDLs/Basin Plan amendment package includes staff reports, an Environmental Checklist, an assessment of the potential environmental impacts of the TMDLs/Basin Plan amendment, and a discussion of alternatives. The TMDLs/Basin Plan amendment, Environmental Checklist, staff reports, and supporting documentation are functionally equivalent to an Environmental Impact Report or Negative Declaration.
25. On August 26, 2005, the Regional Board held a Public Hearing to consider the TMDLs/Basin Plan amendment. Notice of the Public Hearing was given to all interested persons and published in accordance with Water Code Section 13244.
26. The TMDLs/Basin Plan amendment must be submitted for review and approval by the State Water Resources Control Board (SWRCB), Office of Administrative Law (OAL) and U.S. Environmental Protection Agency (USEPA). Once approved by the SWRCB, the amendment is submitted to OAL

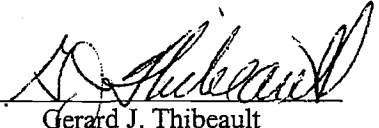

and USEPA. The TMDLs/Basin Plan amendment will become effective upon approval by OAL and USEPA. A Notice of Decision will be filed.

27. The Notice of Filing, the TMDL Report, environmental checklist, and the draft amendment were prepared and distributed to interested individuals and public agencies for review and comment, in accordance with state and federal regulations (23 CCR §3775, 40 CFR-25 and 40 CFR-131).
28. For the purposes of specifying compliance schedules in NPDES permits for effluent limitations necessary to implement these TMDLs, the schedule(s) specified in these TMDLs shall govern, notwithstanding other compliance schedule authorization language in the Basin Plan.

NOW, THEREFORE BE IT RESOLVED THAT:

1. The Regional Board adopts the amendment to the Water Quality Control Plan for the Santa Ana River Basin (Region 8), as set forth in the attachment.
2. The Executive Officer is directed to forward copies of the TMDLs/Basin Plan amendment to the SWRCB in accordance with the requirements of Section §13245 of the California Water Code.
3. The Regional Board requests that the SWRCB approve the TMDLs/Basin Plan amendment, in accordance with Sections §13245 and §13246 of the California Water Code, and forward it to the OAL and U.S. EPA for approval.
4. If, during its approval process, the SWRCB or OAL determines that minor, non-substantive corrections to the language of the amendment are needed for clarity or consistency, the Executive Officer may make such changes, and shall inform the Board of any such changes.
5. The Executive Officer is authorized to sign a Certificate of Fee Exemption in lieu of payment of the California Department of Fish and Game filing fee.

I, Gerard J. Thibeault, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Santa Ana Region, on August 26, 2005.

Gerard J. Thibeault
Executive Officer

ATTACHMENT TO RESOLUTION NO. R8-2005-0001

Amendment to the Santa Ana Region Basin Plan

Chapter 5 - Implementation Plan

(NOTE: The following language is to be added in Chapter 5 of the Basin Plan. If the amendments are approved, corresponding changes will be made to the Table of Contents, the List of Tables, page numbers, and page headers in the plan. Due to the two-column page layout of the Basin Plan, the location of tables in relation to text may change during final formatting of the amendments. For formatting purposes, the maps may be redrawn for inclusion in the Basin Plan, and the final layout may differ from that of the draft.)

Middle Santa Ana River Watershed

The Middle Santa Ana River Watershed covers approximately 488 square miles and lies largely in the southwestern corner of San Bernardino County, and the northwestern corner of Riverside County. A small part of Los Angeles County (Pomona/Claremont area) is also included. This watershed is comprised of three sub-watersheds. The first sub-watershed is the Chino Basin Watershed, which includes portions of San Bernardino County, Los Angeles County, and Riverside County. Surface drainage in this area is directed to Chino Creek and Cucamonga/Mill Creek and is generally southward, from the San Gabriel Mountains toward the Santa Ana River and the Prado Flood Control Basin. The second sub-watershed, the Riverside Watershed, is located in Riverside County. Surface drainage in this area is generally westward from the City of Riverside to the Santa Ana River, Reach 3. The third sub-watershed, the Temescal Canyon Watershed, is also located in Riverside County. Surface drainage in this area is generally northward to Temescal Creek.

Land uses in the Middle Santa Ana River watershed include urban, agriculture, and open space. Although originally developed as an agricultural area, the watershed is being steadily urbanized. Incorporated cities in the Middle Santa Ana River watershed include Pomona, Chino Hills, Upland, Montclair, Claremont, Ontario, Rancho Cucamonga, Rialto, Chino, Fontana, Norco, Corona, and Riverside. In addition, there are several pockets of urbanized unincorporated areas. The current population of the watershed, based upon 2000 census data, is approximately 1.4 million people. The principal remaining agricultural area in the watershed is the area formerly known as the Chino Dairy Preserve. This area is located in the south-central part of the Chino Basin watershed and contains approximately 300,000 cows, which generate the waste equivalent of more than two million people. Recently, the cities of Ontario and Chino annexed the San Bernardino County portions of this area. The remaining portion of the former preserve, which is in Riverside County, remains unincorporated. Open space areas include National Forest lands and State Parks lands.

Middle Santa Ana River Watershed Bacterial Indicator Total Maximum Daily Loads(TMDLs)

Middle Santa Ana River Watershed waterbodies listed on the Clean Water Act Section 303(d) list of impaired waters due to violations of REC1 fecal coliform bacteria objectives are shown in Table 5-9w.

Table 5-9w – Middle Santa Ana River Watershed Waterbodies on the 303(d) List Due to Bacterial Contamination

Waterbody, Reach
Santa Ana River, Reach 3
Chino Creek, Reach 1
Chino Creek, Reach 2
Mill Creek (Prado Area)
Cucamonga Creek, Reach 1
Prado Park Lake

During storm events, these waterbodies receive and transport runoff from urban, agricultural, and open space areas. During dry weather, these waterbodies receive and transport nuisance runoff, primarily from urban areas. Based on monitoring results, and observed waterbody conditions (fish kills and waste-laden stormflows), the Regional Board placed these waterbodies on the 303(d) list of impaired waters due to levels of bacterial indicators that exceeded established objectives for REC1 uses. The listings took place from 1988 to 1998.

A TMDL technical report prepared by Regional Board staff describes the bacterial indicator related problems in the Middle Santa Ana River Watershed waterbodies in greater detail and discusses the technical basis for the TMDLs that follow [Ref. # 1].

A. Middle Santa Ana River Watershed Bacterial Indicator TMDL Numeric Targets

Bacterial indicator numeric targets for the Middle Santa Ana River Watershed waterbodies shown in Table 5-9x are based, in part, on the fecal coliform water quality objective specified in Chapter 4 for the protection of body-contact recreation (REC1) in inland surface waters.

Recognizing that, in the future, *Escherichia coli* (*E. coli*) may be incorporated into the Basin Plan as new bacterial water quality objectives for REC1, alternative numeric targets for *E. coli* are also specified¹. These targets are based on *E. coli* criteria recommended by the U.S. Environmental Protection Agency [Ref #2]. The *E. coli* levels were chosen to roughly correspond to the health risk level associated with the fecal coliform objectives.

The numeric targets for both bacterial indicators incorporate an explicit 10% margin of safety to address uncertainties recognized in the development of the TMDLs.

¹ USEPA is requiring the states to evaluate and incorporate more appropriate bacterial indicators, including *E. coli*, as water quality standards based on its Ambient Water Quality Criteria for Bacteria – 1986. The Regional Board is participating in the efforts of the Storm Water Quality Standards Task Force (SWQSTF), which is evaluating USEPA's bacterial indicator recommendations and REC1 beneficial use designations for waterbodies within the Santa Ana Region, including the Middle Santa Ana River watershed waterbodies. This numeric target and resulting TMDLs, WLAs and LAs will be adjusted accordingly when and if recommendations from the SWQSTF are incorporated into the Basin Plan.

These numeric targets are specified as follows:

Fecal coliform: log mean less than 200 organisms/100 mL based on five or more samples per 30 day period, and not more than 10% of the samples exceed 400 organisms/100 mL for any 30-day period.

***E. coli*: log mean less than 126 organisms/100 mL based on five or more samples per 30-day period, and not more than 10% of the samples exceed 235 organisms/100mL for any 30 day period.**

The fecal coliform numeric targets (and other fecal coliform related provisions of these TMDLs) will become ineffective upon the replacement of the fecal coliform REC1 objectives in the Basin Plan with REC1 objectives based on *E. coli*. Incorporation of new *E. coli* objectives will be considered through the Basin Planning process.

B. Middle Santa Ana River Watershed Bacterial Indicator TMDLs, Wasteload Allocations, Load Allocations and Compliance Dates

As discussed in the technical TMDL Report, the bacterial indicator TMDLs are expressed in terms of density since it is the number of organisms in a given volume of water (i.e., their density), and not their mass that is significant with respect to public health and the protection of beneficial uses. Similarly, the wasteload allocations for point source discharges (WLAs) and load allocations for nonpoint source discharges (LAs) are also based on density. The density-based WLAs and LAs do not add up to equal the TMDLs, since this is not scientifically valid. To achieve the density-based TMDLs, each WLA and LA must meet the density-based TMDL. As indicated in Table 5-9x, the TMDLs, WLAs and LAs also include a 10% margin of safety (see C., below) applied to the existing Basin Plan fecal coliform objective for REC1 for inland surface waters and to the alternative indicator *E. coli* criteria recommended by the U.S. Environmental Protection Agency. Again, the *E. coli* was chosen to correspond with the health risk level associated with the fecal coliform objectives.

WLAs are specified for urban discharges and discharges from Confined Animal Feeding Operations, including stormwater. LAs are specified for runoff from other types of agriculture and from natural sources (open space/undeveloped forest land). TMDLs, WLAs and LAs are specified for both dry weather discharges and wet weather discharges, with separate compliance schedules. An extended schedule for compliance with the wet weather TMDLs is specified in light of the expected increased difficulty in achieving compliance under these conditions.

Table 5-9x – Total Maximum Daily Loads, Waste Load Allocations, and Load Allocations for Bacterial Indicators in Middle Santa Ana River Waterbodies^{a,b,c}

Indicator	Total Maximum Daily Loads for Bacterial Indicators	Waste Load Allocation for Bacterial Indicators in Urban Runoff including stormwater discharges	Waste Load Allocation for Bacterial Indicators in Confined Animal Feeding Operations discharges	Load Allocation for Bacterial Indicators in Agricultural runoff discharges	Load Allocation for Bacterial Indicators from Natural Sources
Dry Summer Conditions: April 1 through October 31, as soon as possible, but no later than December 31, 2015					
Fecal coliform	5-sample/30-day Logarithmic Mean less than 180 organisms/100mL, and not more than 10% of the samples exceed 360 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100mL, and not more than 10% of the samples exceed 360 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100mL, and not more than 10% of the samples exceed 360 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100mL, and not more than 10% of the samples exceed 360 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100mL, and not more than 10% of the samples exceed 360 organisms/100mL for any 30-day period.
E. coli	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.
Wet Winter Conditions: November 1 through March 31, as soon as possible, but no later than December 31, 2025					
Fecal coliform	5-sample/30-day Logarithmic Mean less than 180 organisms/100ml, and not more than 10% of the samples exceed 360 organisms/100ml for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100ml, and not more than 10% of the samples exceed 360 organisms/100ml for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100ml, and not more than 10% of the samples exceed 360 organisms/100ml for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100ml, and not more than 10% of the samples exceed 360 organisms/100ml for any 30-day period.	5-sample/30-day Logarithmic Mean less than 180 organisms/100ml, and not more than 10% of the samples exceed 360 organisms/100ml for any 30-day period.
E. coli	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.	5-sample/30-day Logarithmic Mean less than 113 organisms/100mL, and not more than 10% of the samples exceed 212 organisms/100mL for any 30-day period.

^a To be achieved as soon as possible, but no later than dates specified.

^b TMDLs, WLAs and LAs, include a 10% Margin of Safety

^c The fecal coliform TMDLs, WLAs and LAs become ineffective upon the replacement of the REC1 fecal coliform objectives in the Basin Plan by approved REC1 objectives based on *E. coli*.

C. Margin of Safety

A 10% margin of safety is explicitly incorporated into the Bacterial Indicator TMDLs for the Middle Santa Ana River Watershed to account for unknowns, such as bacterial regrowth, bacteria dilution and organism die-off. As additional data on bacterial dynamics in the Middle Santa Ana River watershed are developed, the margin of safety can be adjusted accordingly.

D. Seasonal Variations/Critical Conditions

The Basin Plan REC1 fecal coliform objectives apply year-round; no distinctions based on climate or other conditions that may affect actual REC1 use are specified². As shown in Table 5-9x, different compliance dates are specified for dry season discharges and wet season discharges. This ensures that dry season recreational beneficial uses are addressed on a priority basis. Additional time is allowed to address complexities associated with the control of wet weather discharges.

E. TMDL Implementation

Implementation is expected to result in compliance with the water quality objectives/numeric targets for fecal coliform and with the numeric targets for *E. coli*. The intent is to ensure protection of the REC1 beneficial uses of Middle Santa Ana River Watershed waterbodies. Collection of additional monitoring data is critical to developing long-term solutions for bacterial indicator control, as well as to consider whether changes to the TMDL are appropriate. With that in mind, the requirements for submittal of plans and schedules to implement the TMDLs take into consideration the need to develop and implement effective short-term solutions, as well as allow for the development of long-term solutions once additional data have been generated.

Implementation of tasks and schedules as specified in Table 5-9y is expected to achieve compliance with the TMDLs and, thereby, water quality standards. Each of these tasks is described below:

² The SWQSTF may recommend changes to the REC1 objectives to reflect conditions, such as high flows, that affect REC1 use. Any such changes will be considered through the Basin Planning process.

Table 5-9y – Middle Santa Ana River Watershed Bacterial Indicator TMDL Implementation Plan/Schedule Due Dates

Task	Description	Compliance Date-As soon As Possible but No Later Than
TMDL Phase 1		
Task 1	Revise Existing Waste Discharge Requirements	(*9 months after BPA approval*)
Task 2	Identify Agricultural Operators	(*1 month after BPA approval*)
Task 3	Develop Watershed-Wide Bacterial Indicator Water Quality Monitoring Program Implement Watershed-Wide Bacterial Indicator Water Quality Monitoring Program	(* 6 months after BPA approval*) Upon Regional Board approval Seasonal reports due May 31 and December 31 of each year Triennial reports due every 3 years beginning with first report due February 15, 2007.

Task 5	Agricultural Discharges 5.1 Develop and Implement Bacterial Indicator Agricultural Source Evaluation Plan 5.2 Develop and Implement Bacterial Indicator Agricultural Source Management Plan	Plan/schedule due 5.1 (*6 months after BPA approval*); 5.2 Dependent on Task 5.1 results (see text)
Task 6	Review of TMDLs/WLAs/LAs	Once every 3 years to coincide with the Regional Board's triennial review, or more frequently as warranted

[Note: BPA => Basin Plan Amendment]

Task 1: Review and/or Revise Existing Waste Discharge Requirements

There are three Waste Discharge Requirements (WDRs) issued by the Regional Board regulating discharge of various types of wastes in the watershed. On or before (**9 months from the effective date of this Basin Plan amendment**), each of these WDRs shall be reviewed and revised as necessary to implement the TMDLs, including the appropriate wasteload allocations, compliance schedules and/or monitoring program requirements.

- 1.1 Waste Discharge Requirements for the San Bernardino County Flood Control and Transportation District, the County of San Bernardino and the Incorporated Cities of San Bernardino County within the Santa Ana Region, Areawide Urban Runoff, NPDES No. CAS 618036 (Regional Board Order No. R8-2002-0012). The current Order has provisions to address TMDL issues (see Task 4, below). In light of these provisions, revision of the Order may not be necessary to address TMDL requirements.
- 1.2 Waste Discharge Requirements for the Riverside County Flood Control and Water Conservation District, the County of Riverside and the Incorporated Cities of Riverside County within the Santa Ana Region, Areawide Urban Runoff, NPDES No. CAS 618033 (Regional Board Order No. R8-2002-0011). The current Order has provisions to address TMDL issues (see Task 4, below). In light of these provisions, revision of the Order may not be necessary to address TMDL requirements.
- 1.3 General Waste Discharge Requirements for Concentrated Animal Feeding Operations (Dairies and Related Facilities) within the Santa Ana Region, NPDES No. CAG018001 (Regional Board Order No. 99-11). Updated waste discharge requirements for Concentrated Animal Feeding Operations are expected to be considered by the Regional Board in 2005. These requirements will include appropriate TMDL requirements.

Other waste discharge requirements may be reviewed and/or revised to address bacterial indicator discharges as appropriate.

Task 2: Identify Agricultural Operators

On or before (**1 month from the effective date of this BPA**), the Regional Board shall develop a list of all known agricultural owners/operators in the Middle Santa Ana River watershed that will be responsible for implementing requirements of these TMDLs. The Regional Board will send a notice to these operators informing them of their TMDL responsibility and alerting them to the potential regulatory consequences of failure to comply.

To implement the agricultural load allocations for non-Concentrated Animal Feeding Operations, monitoring program requirements specified in Task 3 and the agricultural source evaluation studies (Task 5), the Regional Board may issue waste discharge requirements or a waiver of such waste discharge requirements that is conditioned on satisfactory compliance with these TMDL elements.

Task 3: Watershed-Wide Bacterial Indicator Water Quality Monitoring Program

No later than (**6 months from effective date of this Basin Plan amendment**), the US Forest Service, the County of San Bernardino, the County of Riverside, the cities of Ontario, Chino, Chino Hills, Montclair, Rancho Cucamonga, Upland, Rialto, Fontana, Norco, Riverside, and Corona, Pomona and Claremont and

agricultural operators in the watershed, shall as a group, submit to the Regional Board for approval a proposed watershed-wide monitoring program that will provide data necessary to review and update the TMDLs. Data to be collected and analyzed shall address, at a minimum, determination of compliance with the TMDLs, WLAs and LAs.

At a minimum, the stations specified in Tables 5-9z and 5-9aa and shown in Figure 5-6, at the frequency specified in Tables 5-9z and 5-9aa, shall be considered for inclusion in the proposed monitoring plan. If one or more of these monitoring stations are not included, the rationale shall be provided and proposed alternative monitoring locations shall be identified in the proposed monitoring plan. The proposed monitoring plan shall also include a plan to compile streamflow measurements at existing USGS stream gauging stations.

At a minimum, samples shall be analyzed for the following constituents:

- Fecal Coliform
- Escherichia Coliform (*E. coli*)
- Total Suspended Solids
- pH
- Temperature
- Electrical Conductivity
- Dissolved Oxygen
- Turbidity

The proposed monitoring plan shall be implemented upon Regional Board approval at a duly noticed public meeting. Seasonal reports summarizing and including copies of the data collected during the dry season and wet season monitoring periods shall be submitted by May 31 and December 31 of each year. In order to facilitate review and update of the numeric targets and/or the TMDLs, WLAs, LAs, a triennial report summarizing the data collected for the preceding 3 year period and evaluating compliance with the WLAs/LAs shall be submitted every three years, beginning with the first report due February 15, 2007.

In lieu of this coordinated monitoring plan, one or more of the parties identified above may submit a proposed individual or group monitoring plan for Regional Board approval. Any such individual or group monitoring plan is due no later than (* 6 months from effective date of this Basin Plan amendment*) and shall be implemented upon Regional Board approval at a duly noticed public meeting. Seasonal reports summarizing and including copies of the data collected during the dry season and wet season monitoring periods shall be submitted by May 31 and December 31 of each year. In order to facilitate review and update of the numeric targets and/or the TMDLs, WLAs, LAs, a triennial report summarizing the data collected for the preceding 3 year period and evaluating compliance with the WLAs/LAs shall be submitted every three years, beginning with the first report due February 15, 2007.

It may be that implementation of these monitoring requirements will be required through the issuance of Water Code Section 13267 letters to the affected parties. The monitoring plan(s) will be considered by the Regional Board and shall be implemented upon the Regional Board's approval.

Table 5-9z – Watershed Minimum Required Weekly Sampling Station Locations

Station Number	Station Description
C1	Icehouse Canyon Creek
C2	Chino Creek at Schaeffer Avenue
C3	Prado Park Lake at lake outlet
C7	Chino Creek at Central Avenue
C8	Chino Creek at Prado Golf Course
M2	Cucamonga Creek at Regional Plant No. 1
M5	Mill Creek at Chino-Corona Road
S1	Santa Ana River at MWD Crossing
S3	Santa Ana River at Hamner Avenue
T1	Temescal Wash at Lincoln Avenue
TQ1	Tequesquite Arroyo at Palm Avenue

Frequency of sampling:

dry season: weekly

wet season: two 30-day sampling periods during which a minimum of 5 samples are to be collected (at least one sample weekly) and if possible, a minimum of 5 of those samples must be from storm events.

Table 5-9a-a --Additional Watershed Storm Event Sampling Locations

Station Number	Station Description
M3	Bon View Avenue @ Merrill Avenue
M4	Archibald Avenue @ Cloverdale Avenue
G1	Grove Channel @ Pine Avenue
E1	Euclid Avenue Channel @ Pine Avenue

Frequency of sampling: wet weather – one sample/storm event for 5 storm events/year; dry weather – none.

Task 4: Urban Discharges

Phase I urban discharges, including stormwater runoff, include those from the cities and unincorporated communities in the Middle Santa Ana River Watershed. These discharges are regulated under the MS4 NPDES permits identified in Tasks 1.1 and 1.2 (Review and Revise Existing Waste Discharge Requirements), above. The requirements of these NPDES permits differ somewhat and therefore the TMDL implementation requirements that pertain to the permittees under each permit also vary slightly, as shown below³.

4.1 Develop and Implement Bacterial Indicator Urban Source Evaluation Plans

On or before (**6 months from the effective date of this Basin Plan amendment**), the County of San Bernardino, the County of Riverside, the cities of Ontario, Chino, Chino Hills, Montclair, Rancho Cucamonga, Upland, Rialto, Fontana, Norco, Riverside, and Corona, Pomona and Claremont shall develop a Bacterial Indicator Urban Source Evaluation Plan(s) (USEP). This plan shall include steps needed to identify specific activities, operations, and processes in urban areas that contribute bacterial indicators to Middle Santa Ana River Watershed waterbodies. The plan shall also include a proposed schedule for completion of each of the steps identified. The proposed schedules can include contingency provisions that reflect uncertainty concerning the schedule for completion of the SWQSTF work and/or other investigations that may affect the steps that are proposed. The USEP shall be implemented upon Regional Board approval at a duly noticed public meeting.

4.2 Revise the San Bernardino County Municipal Storm Water Management Program (MSWMP)

Provision XVI.3. of Order No. R8-2002-0012 (see 1.1, above) requires the permittees to revise their Municipal Storm Water Management Program (MSWMP) to include TMDL requirements. Revisions to the MSWMP may be necessary based on the results of Task 4.1, Basin Plan amendments to address recommendations of the SWQSTF, or other investigations. Because of uncertainties regarding the timing of completion of these studies, it is not feasible to identify an explicit date whereby the revision of the MSWMP is to be accomplished. Instead, the Executive Officer shall notify the permittees of the need to revise the MSWMP. Within 90 days of notification by the Executive Officer, the permittees shall submit for Regional Board approval, a plan and schedule to review and revise the MSWMP as necessary to incorporate measures to address the results of the USEP and/or other studies. Further review and revision of the MSWMP needed to address these TMDLs shall be completed in accordance with the requirements of Order No. R8-2002-0012 or amendments thereto that are adopted by the Regional Board at a public hearing. The MSWMP revisions shall include schedules for meeting the bacterial indicator wasteload allocations based on the schedule established in these TMDLs. In order to facilitate any needed update of the numeric targets and/or the TMDLs and urban discharge WLAs, the proposed schedule shall take into consideration the Regional Board's triennial review schedule. The permittees shall also provide a proposal and schedule for 1) evaluating the effectiveness of BMPs and other control actions implemented and 2) evaluating compliance with the bacterial indicator waste load allocations for urban runoff. The plan and schedule to review the MSWMP must be implemented upon approval by the Regional Board after public notice and public hearing, or upon approval by the Executive Officer if no significant comments are received during the public notice period.

³ The San Bernardino MS4 permit requires the development and implementation of a Municipal Stormwater Management Program (MSWMP) to address stormwater discharges from existing urban activities. For the Riverside County MS4 permit, the Drainage Area Management Plan (DAMP) addresses stormwater discharges from existing urban activities.

4.3 Revise the Riverside County Drainage Area Management Plan (DAMP)

Provision XIII.B. of Order No. R8-2002-0011 (see 1.2, above) requires the permittees to revise their Drainage Area Management Plan (DAMP) to include TMDL requirements. Revisions to the DAMP may be necessary based on the results of Task 4.1, Basin Plan amendments to address recommendations of the SWQSTF, or other investigations. Because of uncertainties regarding the timing of completion of these studies, it is not feasible to identify an explicit date whereby the revision of the DAMP is to be accomplished. Instead, the Executive Officer shall notify the permittees of the need to revise the DAMP. Within 90 days of notification by the Executive Officer, the permittees shall submit for Regional Board approval, a plan and schedule to review and revise the DAMP as necessary to incorporate measures to address the results of the USEP and/or other studies. Further review and revision of the DAMP needed to address these TMDLs shall be completed in accordance with the requirements of Order No. R8-2002-0011 or amendments/updates thereto that are adopted by the Regional Board at a public hearing. The DAMP revisions shall include schedules for meeting the bacterial indicator wasteload allocations based on the schedule established in these TMDLs. In order to facilitate review and update of the numeric targets and/or the TMDLs and urban discharge WLAs, the proposed schedule shall take into consideration the Regional Board's triennial review schedule. The revised DAMP shall also include a proposal and schedule for 1) evaluating the effectiveness of BMPs and other control actions implemented and 2) evaluating compliance with the bacterial indicator waste load allocations for urban runoff. The plan and schedule to review and revise the DAMP must be implemented upon approval by the Regional Board after public notice and public hearing, or upon approval by the Executive Officer if no significant comments are received during the public notice period.

4.4 Revise the San Bernardino County Water Quality Management Plan (WQMP)

Provision XII.B. 1: of Order No. R8-2002-0012 requires the permittees to develop and submit a WQMP for new developments and significant redevelopments by January 2004 for the Executive Officer's approval. Revisions to the WQMP may be necessary based on the results of Task 4.1, Basin Plan amendments to address recommendations of the SWQSTF, or other investigations. Because of uncertainties regarding the timing of completion of these studies, it is not feasible to identify an explicit date whereby the revision of the WQMP is to be accomplished. Instead, the Executive Officer shall notify the permittees of the need to revise the WQMP. Within 90 days of notification by the Executive Officer, the permittees shall submit for Regional Board approval a plan and schedule to review and revise the WQMP that addresses the bacterial indicator input from new developments and significant redevelopments to assure compliance with the bacterial indicator wasteload allocations for urban runoff. Further review and revision of the WQMP necessary to address TMDL requirements, shall be completed in accordance with the requirements of Order No. R8-2002-0012 or amendments/updates thereto that are adopted by the Regional Board at a public hearing.

4.5 Revise the Riverside County Water Quality Management Plan (WQMP)

Provision VIII.B. of Order No. R8-2002-0011 (see 1.2, above) requires the permittees to develop and submit a WQMP for new developments and significant redevelopments by June 2004 for approval. On September 17, 2004, the Board approved a WQMP developed by the permittees. The approved WQMP includes source control BMPs, design BMPs and treatment control BMPs. Further revisions to the WQMP may be necessary to meet the WLA for urban runoff. Such revisions may be necessary based on the results of Task 4.1, Basin Plan amendments to address recommendations of the SWQSTF, or other investigations. Because of uncertainties regarding the timing of completion of these studies, it is not feasible to identify an explicit date whereby the revision of the WQMP is to be accomplished. Instead, the Executive Officer shall notify the permittees of the need to revise the WQMP. Within 90 days of notification by the Executive

Officer, the permittees shall submit for Regional Board approval a plan and schedule for review and revision of the WQMP that addresses the bacterial indicator input from new developments and significant redevelopments to assure compliance with the bacterial indicator wasteload allocations for urban runoff. Further review and revision of the WQMP necessary to address TMDL requirements, shall be completed in accordance with the requirements of Order No. R8-2002-0011 or amendments/updates thereto that are adopted by the Regional Board at a public hearing.

If the results of studies conducted pursuant to Tasks 3 and 4.1 above demonstrate that either the Phase II non-traditional small MS4 discharges covered under the statewide Waste Discharge Requirements for Stormwater Discharges from Small Municipal Separate Storm Systems (Order No. 2003-0005-DWQ) or industrial discharges from facilities covered by the statewide Industrial Stormwater General Permit (Order 97-03-DWQ) or any Regional Board individual industrial permit, are responsible, to a significant degree, for exceedances of the urban WLAs, the Regional Board will take the appropriate regulatory steps to address these discharges.

Task 5: Agricultural Discharges

Agricultural discharges include stormwater runoff, wastewater release and tailwater runoff from agricultural land uses. Tailwater runoff is irrigation water that runs off of agricultural land. Agricultural land uses include concentrated animal feeding operations and irrigated and dry-land farming in the Middle Santa Ana River Watershed. Concentrated animal feeding operations are regulated under WDRs (see Task 1.3, above); irrigated agriculture and dry-land farming are not currently regulated.

5.1 Develop and Implement Bacterial Indicator Agricultural Source Evaluation Plans

On or before (**6 months from the effective date of this Basin Plan amendment**), concentrated animal feeding facility operators and agricultural operators in the Middle Santa Ana River Watershed shall develop and implement Bacterial Source Agricultural Source Evaluation Plans (AGSEP). These plans shall include steps needed to identify specific activities, operations, and processes in agricultural areas that contribute bacterial indicators to Middle Santa Ana River Watershed waterbodies. The plan shall also include a proposed schedule for completion of each of the steps identified. The proposed schedules can include contingency provisions that reflect uncertainty concerning the schedule for completion of the SWQSTF work and/or other investigations that may affect the steps that are proposed. The AGSEP shall be implemented upon Regional Board approval at a duly noticed public meeting.

The Regional Board expects that the AGSEP will be submitted and implemented pursuant to these TMDL requirements. Where and when necessary to implement these requirements, the Regional Board will utilize appropriate waste discharge requirements including those for concentrated animal feeding operations (see 1.3, above), or other Water Code authorities.

In lieu of a coordinated source evaluation plan, one or more of the parties identified above may submit a proposed individual or group AGSEP to conduct the above studies for areas within their jurisdiction. Any such individual or group plan shall also be submitted for Regional Board approval no later than (**6 months from the effective date of this Basin Plan amendment**). This AGSEP shall be implemented upon Regional Board approval at a duly noticed public meeting.

5.2 Develop and Implement a Bacterial Indicator Agricultural Source Management Plan

Based on the results of Task 5.1 or other studies conducted in the watershed, concentrated animal feeding operators and agricultural operators within the Middle Santa Ana River Watershed shall, as a group, submit a proposed Bacterial Indicator Agricultural Source Management Plan (BASMP). Because of uncertainties regarding the timing of completion of these studies and in recognition that readily identifiable steps may be taken to reduce bacterial discharges from agricultural lands, it is not feasible to identify an explicit date whereby the development and implementation of the BASMP is to be accomplished. Instead, the Executive Officer shall notify agricultural operators of the need to submit the proposed BASMP in whole or to submit plans and schedule to address a subset of tasks identified in the AGSEP. Within 90 days of notification by the Executive Officer, the proposed BASMP, or a subset thereof, shall be submitted. The BASMP, or subset thereof, shall be implemented upon Regional Board approval at a duly noticed public meeting. At a minimum, the BASMP shall include, plans and schedules for the following:

- A. implementation of bacterial indicator controls, BMPs and reduction strategies designed to meet load allocations;
- B. evaluation of effectiveness of BMPs; and
- C. development and implementation of compliance monitoring program(s).

The Regional Board expects that the BASMP will be submitted and implemented pursuant to these TMDL requirements. Where and when necessary to implement these requirements, the Regional Board will utilize appropriate waste discharge requirements or other Water Code authorities.

In lieu of a coordinated plan, one or more of the parties identified above may submit a proposed individual or group BASMP to develop and implement the above plan for areas within their jurisdiction. Any such individual or group plan shall also be submitted for Regional Board approval. Because of uncertainties regarding the timing of completion of these studies and in recognition that readily identifiable steps may be taken to reduce bacterial discharges from agricultural lands, it is not feasible to identify an explicit date whereby the development and implementation of the BASMP is to be accomplished. Instead, the Executive Officer shall notify agricultural operators of the need to submit the proposed BASMP in whole or to submit plans and schedule to address a subset of tasks identified in the AGSEP. Within 90 days of notification by the Executive Officer, the proposed BASMP, or a subset thereof, shall be submitted. This BASMP, or a subset thereof, shall be implemented upon Regional Board approval at a duly noticed public meeting.

Task 6: Review/Revision of the Bacterial Indicator TMDL (TMDL "Re-opener")

The basis for the TMDLs and implementation schedule will be re-evaluated at least once every three years⁴ to determine the need for modifying the load and wasteload allocations, numeric targets and TMDLs. Regional Board staff will continue to review all data and information generated pursuant to the TMDL requirements on an ongoing basis. Based on results generated through the monitoring programs, special studies, modeling analysis, efforts of the Storm Water Quality Standards Task Force⁵ and/or

⁴ The three-year schedule will coincide with the Regional Board's triennial review schedule.

⁵ Stakeholders formed the Storm Water Quality Standards Task Force (Task Force) in 2002 to support review and update of the bacterial quality objectives for REC1 waters and to review the REC1 designations themselves to assure their accuracy. Participants include representatives from the Santa Ana Watershed Project Authority, (SAWPA) flood control agencies from the 3 counties within the Santa Ana Region, POTW dischargers and stormwater staff from various municipalities in the watershed. Environmental groups, Regional Board staff and USEPA staff are also participants. SAWPA staff serve as facilitators for the Task Force.

special studies by one or more responsible parties, changes to the TMDLs, including revisions to the numeric targets, WLAs and LAs, may be warranted. Such changes would be considered through the Basin Plan Amendment process.

The Regional Board is committed to the review of this TMDL every three years, or more frequently if warranted by the results of monitoring and/or other relevant studies

**California Regional Water Quality Control Board
Santa Ana Region**

RESOLUTION NO. R8-2006-0023

Resolution Amending the Water Quality Control Plan for the Santa Ana River Basin to Incorporate a Nutrient
Total Maximum Daily Load (TMDL) for Dry Hydrological Conditions
for Big Bear Lake

WHEREAS, the California Regional Water Quality Control Board, Santa Ana Region (hereinafter, Regional Board), finds that:

1. An updated Water Quality Control Plan for the Santa Ana River Basin (Basin Plan) was adopted by the Regional Board on March 11, 1994, approved by the State Water Resources Control Board (SWRCB) on July 21, 1994, and approved by the Office of Administrative Law (OAL) on January 24, 1995.
2. The Basin Plan specifies the following beneficial uses for Big Bear Lake: cold freshwater habitat (COLD), warm freshwater habitat (WARM), water contact recreation (REC1), non-contact water recreation (REC2), wildlife habitat (WILD), municipal and domestic supply (MUN), agricultural supply (AGR), rare, threatened or endangered species (RARE) and groundwater recharge (GWR).
3. For COLD designated inland surface waters, the Basin Plan specifies the narrative objective that dissolved oxygen levels shall not be depressed below 6 mg/L. For WARM designated inland surface waters, the Basin Plan specifies the narrative objective that dissolved oxygen levels shall not be depressed below 5 mg/L.
4. The narrative objectives pertaining to dissolved oxygen are not being met consistently in Big Bear Lake, as demonstrated by relevant monitoring.
5. The Basin Plan specifies numeric total phosphorus and total inorganic nitrogen water quality objectives for Big Bear Lake. These water quality objectives were based on ambient concentrations of total phosphorus and total inorganic nitrogen as determined in the 1970s. Evidence now indicates that these objectives are not sufficiently stringent to protect beneficial uses and should be revised. Relevant monitoring demonstrates that these objectives are not consistently met in Big Bear Lake.
6. Proliferation of nuisance aquatic plants has been recorded in Big Bear Lake since the 1970s. Nutrient discharges have promoted the growth of aquatic plants. These nuisance aquatic plants serve as both a sink and a source of nutrients.
7. Big Bear Lake's designated beneficial uses adversely impacted by nuisance aquatic plants and low dissolved oxygen levels include COLD, WARM, WILD, REC1, REC2 and RARE.
8. As a result of the beneficial use impacts to Big Bear Lake, the Regional Board listed Big Bear Lake as water quality limited in accordance with Section 303(d) of the Clean Water Act. Section 303(d) requires the establishment of a Total Maximum Daily Load (TMDL) for the pollutant(s) causing the impairment. Phosphorus is the principal nutrient causing the impairment. Section 303(d) also requires the allocation of the TMDL among the sources of nutrient inputs. State law requires an implementation plan and schedule to ensure that the TMDL is met and that compliance with water quality standards is achieved.

9. The Basin Plan amendment shown in the attachment to this Resolution was developed in accordance with Clean Water Act Section 303(d) and Water Code Section 13240 *et seq.* The amendment is proposed for incorporation into Chapter 5 "Implementation", of the Basin Plan. The proposed Basin Plan amendment includes background information concerning the water quality impairment being addressed and the sources of nutrients to Big Bear Lake. The proposed TMDL is supported by a detailed report prepared by Regional Board staff and titled "Staff Report on the Nutrient Total Maximum Daily Loads for Big Bear Lake", June 2005 (hereinafter, "TMDL Report").
10. The Basin Plan amendment specifies a numeric target for total phosphorus. Control of phosphorus is one of the potential methods to ensure compliance with relevant numeric and narrative water quality objectives specified in the Basin Plan, and to prevent adverse beneficial use impacts resulting from the proliferation of nuisance aquatic plants. There is evidence that nitrogen is the limiting nutrient under certain circumstances and that control of nitrogen inputs may be an additional method to address beneficial use impairment in Big Bear Lake. However, due to data and analytical model limitations, it is infeasible to identify an appropriate and achievable nitrogen TMDL, targets and wasteload and load allocations at this time. The Basin Plan amendment requires the collection and evaluation of nitrogen data that will support future revision of the TMDL, if and as necessary.
11. The Basin Plan amendment specifies response numeric targets for chlorophyll a, macrophyte coverage and percentage of nuisance aquatic vascular plant species for Big Bear Lake. These response numeric targets provide a method to track improvements in water quality resulting from reductions in the loading of phosphorus.
12. The numeric targets apply to all hydrological conditions.
13. The Basin Plan amendment specifies a TMDL, wasteload allocations for point source discharges (WLAs), load allocations for nonpoint source discharges (LAs) for total phosphorus for Big Bear Lake for Dry Hydrological Conditions only.
14. The TMDL for Dry Hydrological Conditions specifies a reduction in phosphorus from internal nutrient sources, which are lake sediment and macrophytes. External load dischargers are responsible for reducing their contributions to the internal nutrient loads.
15. The TMDL for Dry Hydrological Conditions does not specify nutrient reductions from external watershed sources, which include resorts, urban discharges and open space/forested lands.
16. The Basin Plan amendment specifies an implementation plan for nutrient reduction. The implementation plan includes compliance schedules for the numeric targets, TMDL, wasteload allocations and load allocations, as well as a monitoring program to track progress toward compliance.
17. The Implementation Plan specifies a requirement for the development of TMDLs, WLAs, and LAs for wet and/or average hydrological conditions once sufficient data are obtained.
18. Given the complex nature of Big Bear Lake, the Implementation Plan specifies the development of a Lake Management Plan that will address competing uses, nutrient reduction strategies and other plans to control nutrient discharges and aquatic plants as appropriate.
19. The Basin Plan amendment will assure the reasonable protection of the beneficial uses of surface waters within the Region and is consistent with the state's antidegradation policy (SWRCB Resolution No. 68-16).

20. The Regional Board has considered the costs associated with implementation of this amendment, as well as costs resulting from failure to implement nutrient control measures necessary to prevent adverse effects on beneficial uses. The implementation plan in the Basin Plan, which includes extended compliance schedules and employs a phased TMDL approach to provide for refinement based on additional studies and analyses, will ensure that implementation expenditures are reasonable and fairly apportioned among dischargers.
21. Review of the potential environmental impacts of the adoption and implementation of the Big Bear Lake Nutrient TMDL was conducted. The adoption of the TMDL would have no direct effect on the environment. The implementation of projects that may be conducted to implement the Nutrient TMDL is expected to have less than significant impacts or less than significant impacts with application of mitigation measures on the following: air quality, biological resources, hazards and hazardous materials, hydrology and water quality, noise, aesthetics and transportation and traffic. As projects to implement the TMDL are developed, specific environmental impacts and mitigation measures to address those impacts are subject to thorough and separate evaluation pursuant to the California Environmental Quality Act (CEQA).
22. Provided that appropriate mitigation is implemented, projects designed and conducted to achieve the TMDL are expected to have less than significant impact, either individually or cumulatively, on fish and/or wildlife species.
23. The adoption of this TMDL is necessary to reduce loadings of nutrients to Big Bear Lake and to address water quality impairments that arise therefrom.
24. The proposed amendment meets the "Necessity" standard of the Administrative Procedure Act, Government Code, Section 11352, subdivision (b).
25. The Regional Board submitted the relevant technical documents that serve as the basis for the proposed amendment to an external scientific review panel and has considered the comments and recommendations of that panel in drafting the amendment.
26. The proposed amendment will result in revisions to the Basin Plan Chapter 5 "Implementation".
27. The Regional Board discussed this matter at a workshop conducted on August 26, 2005 after notice was given to all interested persons in accordance with Section 13244 of the California Water Code. Based on the discussion at those workshops, the Board directed staff to prepare the appropriate Basin Plan amendment and related documentation to incorporate the Big Bear Lake Nutrient TMDL.
28. The Regional Board prepared and distributed written reports (staff reports) regarding adoption of the Basin Plan amendment in accordance with applicable state and federal environmental regulations (California Code of Regulations, Section 3775, Title 23, and 40 CFR Parts 25 and 131).
29. The process of basin planning has been certified by the Secretary for Resources as exempt from the requirement of the California Environmental Quality Act (Public Resources Code Section 21000 et seq.) to prepare an Environmental Impact Report or Negative Declaration. The Basin Plan amendment package includes staff reports, an Environmental Checklist, an assessment of the potential environmental impacts of the Basin Plan amendment, and a discussion of alternatives. The Basin Plan amendment, Environmental Checklist, staff reports, and supporting documentation are functionally equivalent to an Environmental Impact Report or Negative Declaration.

30. On April 21, 2006, the Regional Board held a Public Hearing to consider the Basin Plan amendment. Notice of the Public Hearing was given to all interested persons and published in accordance with Water Code Section 13244.
31. The Basin Plan amendment must be submitted for review and approval by the State Water Resources Control Board (SWRCB), Office of Administrative Law (OAL) and U.S. Environmental Protection Agency (USEPA). Once approved by the SWRCB, the amendment is submitted to OAL and USEPA. The Basin Plan amendment will become effective upon approval by OAL. A Notice of Decision will be filed.
32. The Notice of Filing, the TMDL Report, environmental checklist, and the draft amendment were prepared and distributed to interested individuals and public agencies for review and comment, in accordance with state and federal regulations (23 CCR §3775, 40 CFR 25 and 40 CFR 131).
33. For the purposes of specifying compliance schedules in NPDES permits for effluent limitations necessary to implement this TMDL, the schedule(s) specified in this TMDL shall govern, notwithstanding other compliance schedule authorization language in the Basin Plan.

NOW, THEREFORE BE IT RESOLVED THAT:

1. The Regional Board adopts the amendment to the Water Quality Control Plan for the Santa Ana River Basin (Region 8), as set forth in the attachment.
2. The Executive Officer is directed to forward copies of the Basin Plan amendment to the SWRCB in accordance with the requirements of Section §13245 of the California Water Code.
3. The Regional Board requests that the SWRCB approve the Basin Plan amendment, in accordance with Sections §13245 and §13246 of the California Water Code, and forward it to the OAL and U.S. EPA for approval.
4. If, during its approval process, Regional Board staff, SWRCB or OAL determines that minor, non-substantive corrections to the language of the amendment are needed for clarity or consistency, the Executive Officer may make such changes, and shall inform the Board of any such changes.
5. The Executive Officer is authorized to sign a Certificate of Fee Exemption in lieu of payment of the California Department of Fish and Game filing fee.

I, Gerard J. Thibeault, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Santa Ana Region, on April 21, 2006.

Gerard J. Thibeault
Executive Officer

ATTACHMENT TO RESOLUTION NO. R8-2006-0023

(NOTE: The following language will be inserted into Chapter 5 of the Basin Plan. Corresponding changes will be made to the Table of Contents, the List of Tables, page numbers, and page headers in the plan. Due to ongoing revisions of the Basin Plan layout, the location of tables in relation to text may change during final formatting of the amendments. For formatting purposes, the maps may be redrawn for inclusion in the Basin Plan, and the final layout may differ from that of the draft.)

Chapter 5 - Implementation Plan, Page 5-42

Big Bear Lake

Big Bear Lake, located in the San Bernardino Mountains, was created by the construction of the Bear Valley Dam in 1884. The Lake has a surface area of approximately 3,000 acres, a storage capacity of 73,320 acre-ft and an average depth of 24 feet. The lake reaches its deepest point of 72 feet at the dam. The Big Bear Lake drainage basin encompasses 37 square miles and includes more than 10 streams. Local stream runoff and precipitation on the Lake are the sole source of water supply to the Lake. The spillway altitude is 6,743.2 feet. The major inflows to the lake are creeks, including Rathbone (Rathbun) Creek, Summit Creek, and Grout Creek. Outflow from the Lake is to Bear Creek, which is tributary to the Santa Ana River at about the 4,000-foot elevation level. Twelve percent of Big Bear Lake's drainage basin consists of the Lake itself. The US Forest Service is the largest landowner in the Big Bear area. Two ski resorts, Bear Mountain and Snow Summit, lease land from the Forest Service.

The beneficial uses of Big Bear Lake include cold freshwater habitat (COLD), warm freshwater habitat (WARM), water contact recreation (REC1), non-contact water recreation (REC2), municipal and domestic supply (MUN), agriculture supply (AGR), groundwater recharge (GWR), wildlife habitat (WILD) and rare, threatened or endangered species (RARE).

Big Bear Lake is moderately eutrophic. During the summer months, deeper water may exhibit severe oxygen deficits. Nutrient enrichment has resulted in the growth of aquatic plants, which has impaired the fishing, boating, and swimming uses of the lake. To control this vegetation, mechanical harvesters are used to remove aquatic plants, including the roots.

Toxics may be entering the Big Bear Lake watershed and accumulating in aquatic organisms and bottom sediments at concentrations that are of concern, not only for the protection of aquatic organisms, but for the protection of human health as well. Past Toxic Substances Monitoring Program data have indicated the presence of copper, lindane, mercury, zinc, and PCBs in fish tissue.

During 1992-93, the Regional Board conducted a Phase I Clean Lakes study (Section 314 of the Clean Water Act) to evaluate the current water quality condition of the lake and its major tributaries [Ref. 20]. The focus of the study was to identify the tributaries responsible for inputs of toxics and nutrients. As a result of data collected in the Clean Lakes Study, Big Bear Lake and specific tributaries were placed on the 1994 Clean Water Act Section 303(d) List of Water Quality Limited Segments for the reasons indicated in Table 5-9a-b.

Table 5-9a-b

Big Bear Lake Watershed Waterbodies on the
 1994 303(d) List of Impaired Waters

WATERBODY	STRESSOR
Big Bear Lake	nutrients
	noxious aquatic plants
	sedimentation/siltation
	metals
	copper
Rathbone (Rathbun) Creek	mercury
	nutrients
Grout Creek	sedimentation/siltation
	metals
Summit Creek	nutrients
	nutrients
Knickerbocker Creek	metals
	pathogens

In 2000, the Regional Board convened a TMDL workgroup to assist in the development of Total Maximum Daily Loads for the Big Bear Lake watershed. The Big Bear Municipal Water District, a key contributor to the workgroup, created the Big Bear Lake TMDL Task Force, including representatives of the District, Regional Board staff, the San Bernardino County Flood Control District, the City of Big Bear Lake, the Big Bear Area Regional Wastewater Authority, the State of California, Department of Transportation (Caltrans), the US Forest Service and the Big Bear Mountain Resorts. Initial TMDL development efforts were focused on nutrients, leading to Regional Board adoption of a nutrient TMDL for dry hydrological conditions for Big Bear Lake in 2006. Nutrient TMDLs for wet and/or average hydrological conditions will be incorporated in the Basin Plan when these TMDLs are developed in the future. As shown in Table 5-9a-f, the development of these TMDLs is a requirement of the adopted TMDL implementation plan for the nutrient TMDL for dry hydrological conditions.

1. Big Bear Lake Nutrient Total Maximum Daily Loads (TMDLs)

Past studies, starting in 1968/1969, have shown that Big Bear Lake is moderately eutrophic and that the limiting nutrient is generally phosphorus. In Big Bear Lake, nutrients (nitrogen and phosphorus) are available in the water column and sediment and are taken up by aquatic macrophytes and algae. Nutrients are also bound in living and dead organic material, primarily macrophytes and algae. Decomposition of this organic material, as well as macrophyte and algal respiration, consumes dissolved oxygen, resulting in the depletion of dissolved oxygen from the water column. Oxygen depletion in the hypolimnion results in anoxic conditions, leading to periodic fish kills in Big Bear Lake. Oxygen depletion also results in the release of nutrients from the sediment into the water column, promoting more algae and aquatic macrophyte production. Nutrients released by plant decomposition are cycled back into a bioavailable form.

Although aquatic macrophytes provide protection from shoreline erosion, habitat for fish and other aquatic biota and waterfowl habitat, excessive growth of noxious and nuisance species, particularly Eurasian watermilfoil (*Myriophyllum spicatum*) impairs recreational uses of the Lake and reduces plant and animal species and habitat diversity.

As stated above, development of nutrient TMDLs to address these problems was initiated in 2000. In this process, it was recognized that insufficient data for wet or average hydrological conditions were available to allow calibration of the lake water quality model used to calculate the TMDL. Accordingly, a TMDL was developed to address dry hydrologic conditions only (see Section 1.B., below). This TMDL was adopted by the Regional Board in 2006 and became effective on August 21, 2007. The implementation plan included with this TMDL specifies a requirement for the development of nutrient TMDLs for wet and/or average hydrological conditions.

A key step in the development of the nutrient TMDL was the identification of the numeric targets to be achieved. The numeric targets, identified in Section 1.A., below, do not vary based upon hydrological condition. Like the approved TMDL for dry hydrological conditions, the TMDLs for wet and/or average hydrological conditions that will be developed are expected to assure also that these numeric targets are achieved. Indeed, since the TMDL for dry hydrological conditions was developed to meet the targets under the critical, worst-case conditions, consistent compliance with these targets is expected to be achieved even in the absence of TMDLs for wet/average hydrological conditions, given the greater lake volume and dilution anticipated under wetter conditions. It is recognized that future modifications to the targets may be found necessary.

1. A. Numeric Targets

As shown in Table 5-9a-c, both "causal and response" numeric targets are specified for Big Bear Lake. The causal target is for phosphorus. Phosphorus is the primary limiting nutrient in Big Bear Lake¹. Response targets include macrophyte coverage, percentage of nuisance aquatic vascular plant species and chlorophyll *a* concentration. These response targets are more direct indicators of impairment and are specified to assess and track water quality improvements in Big Bear Lake.

A weight of evidence approach will be used to assess compliance with the TMDL, which means that data pertaining to all the numeric targets will be evaluated and non-compliance with one target will not automatically imply non-compliance with the TMDL.

¹ There is evidence that nitrogen is a limiting nutrient under certain conditions. However, given data and analytical limitations, no nitrogen targets are specified. Nitrogen monitoring is required as part of this TMDL. The data will be used to specify nitrogen targets in the future, as warranted.

Table 5-9a-c
 Big Bear Lake Nutrient TMDL Numeric Targets^a

Indicator	Target Value
Total P concentration	Annual average ^b no greater than 35 µg/L; to be attained no later than 2015 (dry hydrological conditions), 2020 (all other times) ^c
Macrophyte Coverage	30-40% on a total lake area basis; to be attained by 2015 (dry hydrological conditions), 2020 (all other times) ^{c, d}
Percentage of Nuisance Aquatic Vascular Plant Species	95% eradication on a total area basis of Eurasian Watermilfoil and any other invasive aquatic plant species; to be attained no later than 2015 (dry hydrological conditions), 2020 (all other times) ^{c, d}
Chlorophyll <i>a</i> concentration	Growing season ^e average no greater than 14 µg/L; to be attained no later than 2015 (dry hydrological conditions), 2020 (all other times) ^c

^a Compliance with the targets to be achieved as soon as possible, but no later than the date specified

^b Annual average determined by the following methodology: the nutrient data from both the photic composite and discrete bottom samples are averaged by station number and month; a calendar year average is obtained for each sampling location by averaging the average of each month; and finally, the separate annual averages for each location are averaged to determine the lake-wide average. The open-water sampling locations used to determine the annual average are MWDL1, MWDL2, MWDL6, and MWDL9 (see 1.B.4. Implementation, Task 4.2, Table 5-9a-i).

^c Compliance date for wet and/or average hydrological conditions may change in response to approved TMDLs for wet/average hydrological conditions.

^d Calculated as a 5-yr running average based on measurements taken at peak macrophyte growth as determined in the Aquatic Plant Management Plan (see 1.B.4. Implementation, Task 6C)

^e Growing season is the period from May 1 through October 31 of each year. The open-water sampling locations used to determine the growing season average are MWDL1, MWDL2, MWDL6 and MWDL9 (see 1.B.4. Implementation, Task 4.2, Table 5-9a-i). The chlorophyll *a* data from the photic samples are averaged by station number and month; a growing season average is obtained for each sampling location by averaging the average of each month; and finally, the separate growing season averages for each location are averaged to determine the lake-wide average.

1.B. Big Bear Lake Nutrient Total Maximum Daily Load (TMDL) for Dry Hydrological Conditions

The TMDL technical report [Ref. #1] describes in detail the technical basis for the TMDL for Dry Hydrological Conditions that follow.

1. B. 1. Nutrient TMDL, WLAs and LAs and Compliance Dates – Dry Hydrological Conditions

A TMDL, and the WLAs and LAs necessary to achieve it, are established for total phosphorus for dry hydrological conditions only. As stated above, phosphorus and nitrogen are the nutrients that cause beneficial use impairment in Big Bear Lake. Dry hydrological conditions are defined by the conditions observed from 1999-2003; that is, average tributary inflow to Big Bear Lake ranging from 0 to 3,049 AF, average lake levels ranging from 6671 to 6735 feet and annual precipitation ranging from 0 to 23 inches. TMDLs, WLAs and LAs for wet and/or average hydrological conditions will be established as part of the TMDL Phase 2 activities once additional data have been collected (see 1.B.4. TMDL Implementation, Task 9).

The phosphorus TMDL for Big Bear Lake for dry hydrological conditions is shown in Table 5-9a-d. Wasteload allocations for point source discharges and load allocations for nonpoint source discharges are shown in Table 5-9a-e.

Table 5-9a-d

Big Bear Lake Nutrient TMDL for Dry Hydrological Conditions

	Total Phosphorus (lbs/yr)^b
TMDL ^a	26,012

^a Compliance to be achieved as soon as possible, but no later than December 31, 2015.

^b Specified as an annual average for dry hydrological conditions only.

Table 5-9a-e
 Big Bear Lake
 Phosphorus Wasteload and Load Allocations for Dry Hydrological Conditions

Big Bear Lake Nutrient TMDL for Dry Hydrological Conditions	Total Phosphorus Load Allocation (lbs/yr) ^{a, b}
TMDL	26,012
WLA	475
Urban	475
LA	25,537
Internal Sediment	8,555
Internal macrophyte	15,700
Atmospheric Deposition	1,074
Forest	175
Resort	33

^a Allocation compliance to be achieved as soon as possible, but no later than December 31, 2015.

^b Specified as an annual average for dry hydrological conditions only.

1.B.2. Margin of Safety

The Big Bear Lake Nutrient TMDL for Dry Hydrological Conditions includes an implicit margin of safety (MOS) as follows:

1. The derivation of numeric targets based on the 25th percentile of nutrient data;
2. The use of conservative assumptions in modeling the response of Big Bear Lake to nutrient loads.

1. B.3. Seasonal Variations/Critical Conditions

The critical condition for attainment of aquatic life and recreational uses in Big Bear Lake occurs during the summer and during dry years, when nutrient releases from the sediment are greatest and water column concentrations increase. Macrophyte biomass peaks in the summer/early fall. Recreational uses of the lake are also highest during the summer. This nutrient TMDL for Big Bear Lake is focused on the critical dry hydrological conditions and, in particular, on the control of the internal sediment loads that dominate during these periods. This is the first phase of TMDLs needed to address eutrophication in Big Bear Lake. The next phase will include collection of data needed to refine the in-lake and watershed models (see 1.B.4. TMDL Implementation, Task 6A) and to develop TMDLs that address other hydrological conditions (see 1.B.4. TMDL Implementation, Task 9). TMDLs for wet and average hydrological conditions will be developed to address external loading that contributes to the nutrient reservoir in the

lake and thus eutrophic conditions, particularly during the critical dry periods. However, it is important to note again that since the TMDL for dry hydrological conditions was developed to meet the numeric targets under the critical, worst-case conditions, consistent compliance with these targets is expected to be achieved even in the absence of TMDLs for wet/average hydrological conditions, given the greater lake volume and dilution anticipated under wetter conditions.

The TMDL recognizes that different nutrient inflow and cycling processes dominate the lake during different seasons. These processes were simulated in the in-lake model using data collected during all seasons over a multi-year period. Thus, the model results reflect all seasonal variations. The phosphorus numeric target is expressed as an annual average, while the chlorophyll *a* numeric target is expressed as a growing season average. The intent is to set targets that will, when achieved, result in improvement of the trophic status of Big Bear Lake year-round.

Compliance with numeric targets will ensure water quality improvements that prevent excessive algae blooms and fish kills, particularly during the critical summer period when these problems are most likely to occur.

1.B.4. TMDL Implementation

Table 5-9a-f outlines the tasks and schedules to implement the TMDL for Dry Hydrological Conditions. Each of these tasks is described below.

Table 5-9a-f

Big Bear Lake Nutrient TMDL Implementation
 Plan/Schedule Report Due Dates

Task	Description	Compliance Date-As soon As Possible but No Later Than
TMDL Phase 1		
Task 1	Establish New Waste Discharge Requirements for Nutrient Sources	February 29, 2008
Task 2	Establish New Waste Discharge Requirements for Lake Restoration Activities	February 28, 2009
Task 3	Revise Existing Waste Discharge Requirements	February 29, 2008
Task 4	Nutrient Water Quality Monitoring Program 4.1 Watershed-wide Nutrient Monitoring Plan(s) 4.2 Big Bear Lake Nutrient Monitoring Plan(s)	Plan/schedule due November 30, 2007 Annual reports due February 15
Task 5	Atmospheric Deposition Determination	Plan/schedule due August 31, 2008
Task 6	Big Bear Lake – Lake Management Plan, including: 6A. Big Bear Lake and Watershed Model Updates 6B. Big Bear Lake In-Lake Sediment Nutrient Reduction Plan 6C. Big Bear Lake Aquatic Plant Management Plan	Plan/schedule due August 31, 2008 Annual reports due February 15
TMDL Phase 2		
Task 7	Review/Revision of Big Bear Lake Water Quality Standards 7.1 Review/Revise Nutrient Water Quality Objectives 7.2 Development of biocriteria 7.3 Development of natural background definition	December 31, 2015
Task 8	Review Big Bear Lake Tributary Data	December 31, 2008
Task 9	Develop TMDLs, WLAs and LAs for wet and/or average hydrological conditions	December 31, 2012
Task 10	Review of TMDL/WLAs/Las	Once every 3 years

Task 1: Establish New Waste Discharge Requirements for Nutrient Sources

On or before February 29, 2008, the Regional Board shall issue the following new waste discharge requirements

- 1.1 Waste Discharge Requirements (WDRs) or Conditional Waiver of WDRs to the US Forest Service to incorporate the nutrient load allocations, compliance schedule and monitoring and reporting requirements for Forested Areas.

Other nutrient discharges will be addressed and permitted as appropriate.

Task 2: Establish New Waste Discharge Requirements for Lake Restoration Activities

On or before February 28, 2009, the Regional Board shall issue the following new waste discharge requirements

NPDES Permit to the US Forest Service, the State of California, Department of Transportation (Caltrans), the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake, and Big Bear Mountain Resorts for Lake restoration activities; including, but not limited to alum treatment and/or herbicide treatment. Requirements specified in these Waste Discharge Requirements, shall be developed using the Aquatic Plant Management Plan and Schedule submitted pursuant to Task 6C.

Task 3: Review and/or Revise Existing Waste Discharge Requirements

Waste Discharge Requirements (WDRs) have been issued by the Regional Board regulating discharge of various types of wastes in the Big Bear Lake watershed. On or before February 29, 2008, these WDRs shall be reviewed and revised as necessary to incorporate the nutrient wasteload allocations, compliance schedule and TMDL monitoring and reporting requirements.

- 3.1 Waste Discharge Requirements for the San Bernardino County Flood Control and Transportation District, the County of San Bernardino and the Incorporated Cities of San Bernardino County within the Santa Ana Region, Areawide Urban Runoff, NPDES No. CAS 618036 (Regional Board Order No. R8-2002-0012). The current Order has provisions to address TMDL issues. In light of these provisions, revision of the Order may not be necessary to address TMDL requirements.
- 3.2 State of California, Department of Transportation (Caltrans) Stormwater Permit Provision E.1 of Order No. 99-06-DWQ requires Caltrans to maintain and implement a Storm Water Management Plan (SWMP). Annual updates of the SWMP needed to maintain an effective program are required to be submitted to the State Water Resources Control Board.

Provision E.2 of Order No. 99-06-DWQ requires Caltrans to submit a Regional Workplan by April 1 of each year for the Executive Officer's approval. As part of the annual update of the SWMP and Regional Workplan, Caltrans shall submit plans and schedules for conducting the monitoring and reporting requirements specified in Task 4 and the special studies required in Task 6.

Task 4: Monitoring

4.1 Watershed-wide Nutrient Water Quality Monitoring Program

No later than November 30, 2007, the US Forest Service, the State of California, Department of Transportation (Caltrans), the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake and Big Bear Mountain Resorts shall, as a group, submit to the Regional Board for approval a proposed watershed-wide nutrient monitoring program that will provide data necessary to review and update the Big Bear Lake Nutrient TMDL, to determine specific sources of nutrients and to develop TMDLs for other hydrological conditions. Data to be collected and analyzed shall address, at a minimum, determination of compliance with the phosphorus dry condition TMDL, including the WLAs and LAs, and with the existing total inorganic nitrogen (TIN) objective.

At a minimum, the proposed plan shall include the collection of samples at the stations specified in Table 5-9a-g and shown in Figure 5-7, at the frequency specified in Table 5-9a-h. Modifications to the required sampling stations, sampling frequencies and constituents to be monitored (see below) will be considered upon request by the stakeholders, accompanied by a report that describes the rationale for the proposed changes and identifies recommended alternatives. In addition to water quality samples, every two weeks on a year-round basis, visual monitoring (including documenting flow type and stage) determinations shall be made at all stations shown in Table 5-9a-g. Flow measurements will be required each time water quality samples are obtained.

At a minimum, samples shall be analyzed for the following constituents:

- Total nitrogen
- Nitrate + nitrite nitrogen
- Total phosphorus
- Total dissolved phosphorus
- Suspended sediment concentration
- Chlorophyll *a*
- Dissolved oxygen
- Alkalinity
- Bedload concentration
- Total nitrogen in sediment
- Ammonia nitrogen
- Total dissolved nitrogen
- Ortho-phosphate (SRP)
- Temperature
- Turbidity
- pH
- Conductivity
- Hardness
- Grain size
- Total phosphorus in sediment

Note: Chlorophyll *a* to be collected and analyzed only from May 1- October 31 of each year at the frequencies described in Table 5-9a-h; chlorophyll *a* sampling not required at Bear Creek outlet.

In addition, the proposed plan shall include a proposed plan and schedule for development of a Big Bear Lake Sedimentation Processes Plan for the determination of nutrient loads associated with sediment. At a minimum, the proposed plan shall include the placement of sediment traps at the mouths of Rathbun, Knickerbocker, Grout and Boulder Creeks to determine the rate of influx of sediment and particulate nutrients to Big Bear Lake, as specified in Table 5-9a-g and shown in Figure 5-7, at the specified frequency indicated in Table 5-9a-h. Modifications to the required sampling stations, sampling frequencies and constituents to be monitored will be considered upon request by the stakeholders, accompanied by a report that describes the rationale for the proposed changes and identifies recommended alternatives. The proposed monitoring plan shall be implemented upon Regional Board approval at a duly noticed public meeting. An annual report

summarizing the data collected for the year and evaluating compliance with the TMDL/WLAs/LAs shall be submitted by February 15 of each year.

In lieu of this coordinated monitoring plan, one or more of the parties identified above may submit a proposed individual or group monitoring plan for Regional Board approval. Any such individual or group monitoring plan is due no later than November 30, 2007 and shall be implemented upon Regional Board approval at a duly noticed public meeting. An annual report of data collected pursuant to approved individual/group plan(s) shall be submitted by February 15 of each year. The report shall summarize the data and evaluate compliance with the TMDL/WLAs/LAs.

Table 5-9a-g

Big Bear Lake Watershed
 Minimum Required Sampling Station Locations

Station Number	Station Description
MWDC2	Bear Creek Outlet
MWDC3	Grout Creek at Hwy 38
MWDC4	Rathbun Creek at Sandalwood Ave.
MWDC5	Summit Creek at Swan Dr.
MWDC6	Rathbun Creek below the Zoo
MWDC8	Knickerbocker Creek at Hwy 18
MWDC13	Boulder Creek at Hwy 18

Note: Bear Creek outlet to be sampled monthly from March -November

At a minimum, samples shall be analyzed at the frequencies specified in Table 5-9a-h:

Table 5-9a-h

Big Bear Lake Watershed
 Sampling Frequency

Flow type	Months monitoring is required	Frequency
Baseflow	January 1 – December 31	Once/month when baseflow is present;
Snowmelt	January 1 – May 31 ¹	Varied -See note 2 below
Storm events	January 1 – December 31	3 storms per year ³

¹ Sampling to begin after the first substantial snowfall resulting in an accumulation of 1.0 inch or more of snow

² Samples to be collected daily for the first three days of the snowmelt period. If ambient air temperatures remain above freezing after three days have passed, snowmelt sampling will then be performed once a week for the following three weeks or until the snowmelt period ceases. Snowmelt cessation will be determined by one of the following: a) ambient air temperatures drop below freezing during most of the day; or b) a storm/rain precipitation event occurs after the snowmelt event was initiated. Beginning March 15th of each year, snowmelt flows will most likely be continuous since ambient air temperatures will usually remain above freezing. From March 15th through May 31 of each year, snowmelt sampling events will be conducted daily for the first two days of a snowmelt event and then once a week thereafter until the spring runoff period has ended or the tributary station location shows no signs of daily flows for one week. Flow status will be evaluated in the afternoon, when ambient air temperatures are highest and flow potential is greatest.

³ Two storm events to be sampled during October – March; 1 storm event to be sampled during April – September. For each storm event, eight samples across the hydrograph are to be collected.

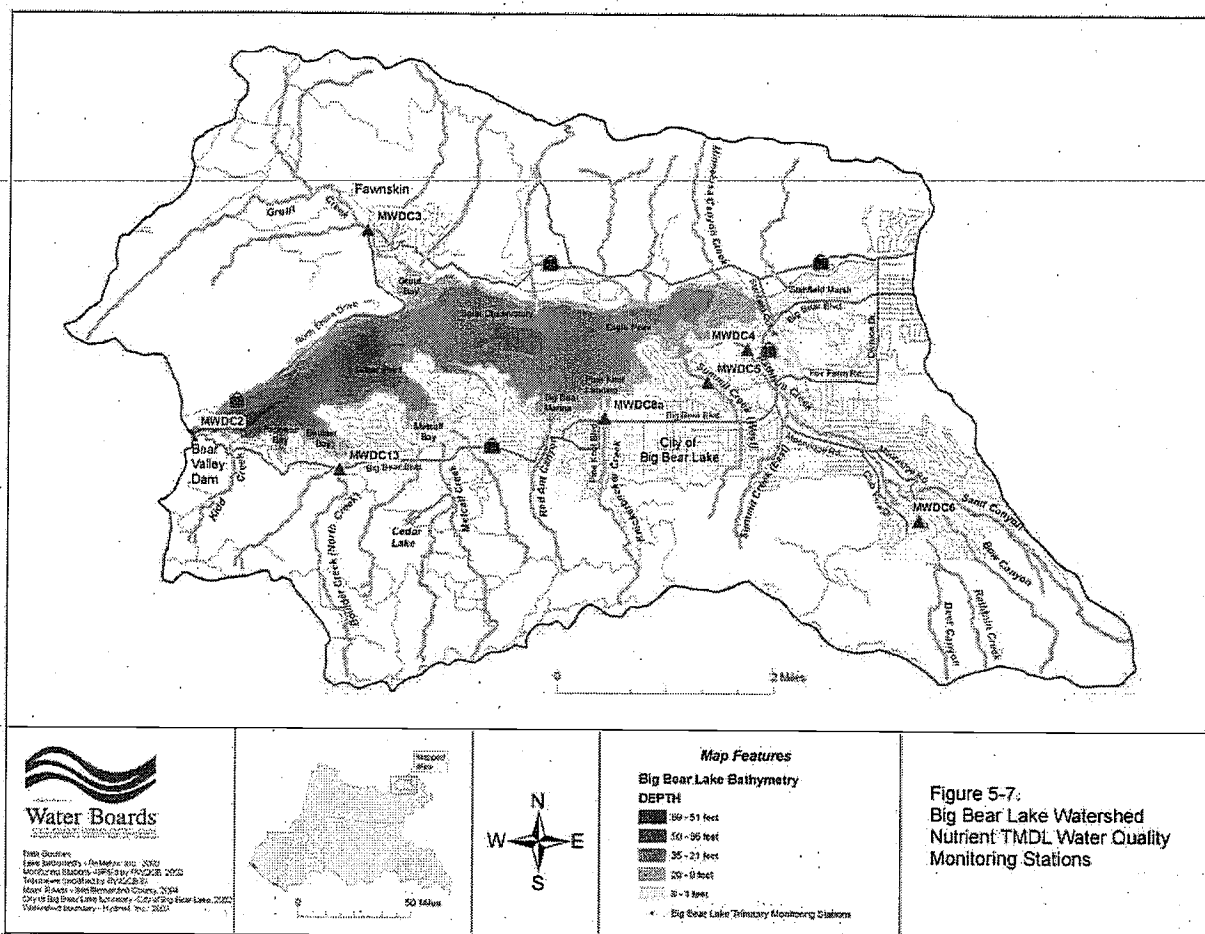

Figure 5-7 – Big Bear Lake Watershed Nutrient TMDL Water Quality Stations

4.2 Big Bear Lake: In-Lake Nutrient Monitoring Program

No later than November 30, 2007, the US Forest Service, the State of California, Department of Transportation (Caltrans), the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake, and Big Bear Mountain Resorts shall, as a group, submit to the Regional Board for approval a proposed Big Bear Lake nutrient monitoring program that will provide data necessary to review and update the Big Bear Lake Nutrient TMDL, and to develop TMDLs for other hydrological conditions. Data to be collected and analyzed shall address, at a minimum: (1) determination of compliance with phosphorus and chlorophyll *a* numeric targets; (2) determination of compliance with the existing total inorganic nitrogen (TIN) objective; and (3) refinement of the in-lake model for the purposes of TMDL review and development.

At a minimum, the proposed plan shall include the collection of samples at the stations specified in Table 5-9a-i and shown in Figure 5-8, at the specified frequency indicated in Table 5-9a-i. Modifications to the required sampling stations, sampling frequencies and constituents to be monitored (see below) will be considered upon request by the stakeholders, accompanied by a report that describes the rationale for the

proposed changes and identifies recommended alternatives. With the exception of hardness, alkalinity, total organic carbon (TOC), dissolved organic carbon (DOC), and chlorophyll *a*, each sample to be analyzed shall be collected as a photic zone composite (from the surface to 2 times the secchi depth) and as a bottom discrete (0.5 meters off the surface bottom) sample. Hardness, alkalinity, TOC, DOC, and chlorophyll *a* shall be collected as photic zone composites. Dissolved oxygen, water temperature, turbidity, specific conductance, and pH shall be measured at 1-meter intervals from the surface to 0.5 meters from the bottom using a multi-parameter water quality meter. Water clarity shall be measured with a secchi disk.

At a minimum, in-lake samples must be analyzed for the following constituents:

- Specific conductance
- Water temperature
- Chlorophyll *a*
- Total nitrogen
- Nitrate +nitrite nitrogen
- Total phosphorus
- Total hardness
- Total dissolved phosphorus
- Dissolved organic carbon (DOC)
- Total dissolved nitrogen
- Dissolved oxygen
- Water clarity (secchi depth)
- Ammonia nitrogen
- Alkalinity
- Turbidity
- Ortho-phosphate (SRP)
- Total suspended solids (TSS)
- pH
- Total dissolved solids (TDS)
- Total organic carbon (TOC)

The monitoring plan shall be implemented upon Regional Board approval at a duly noticed public meeting. An annual report summarizing the data collected for the year and evaluating compliance with the TMDL/WLAs/LAs and numeric targets shall be submitted by February 15 of each year.

Table 5-9a-i

Big Bear Lake Minimum Required Sampling Station Locations

Station Number	Station Description
MWDL1	Big Bear Lake – Dam
MWDL2	Big Bear Lake – Gilner Point
MWDL6	Big Bear Lake – Mid Lake Middle
MWDL9	Big Bear Lake – Stanfield Middle

Frequency of sampling at all stations: for all constituents except TOC and DOC, monthly from March – November; bi-weekly (i.e., every other week) from June 1 through October 31. TOC and DOC to be monitored four times per year (quarterly) from January through December.

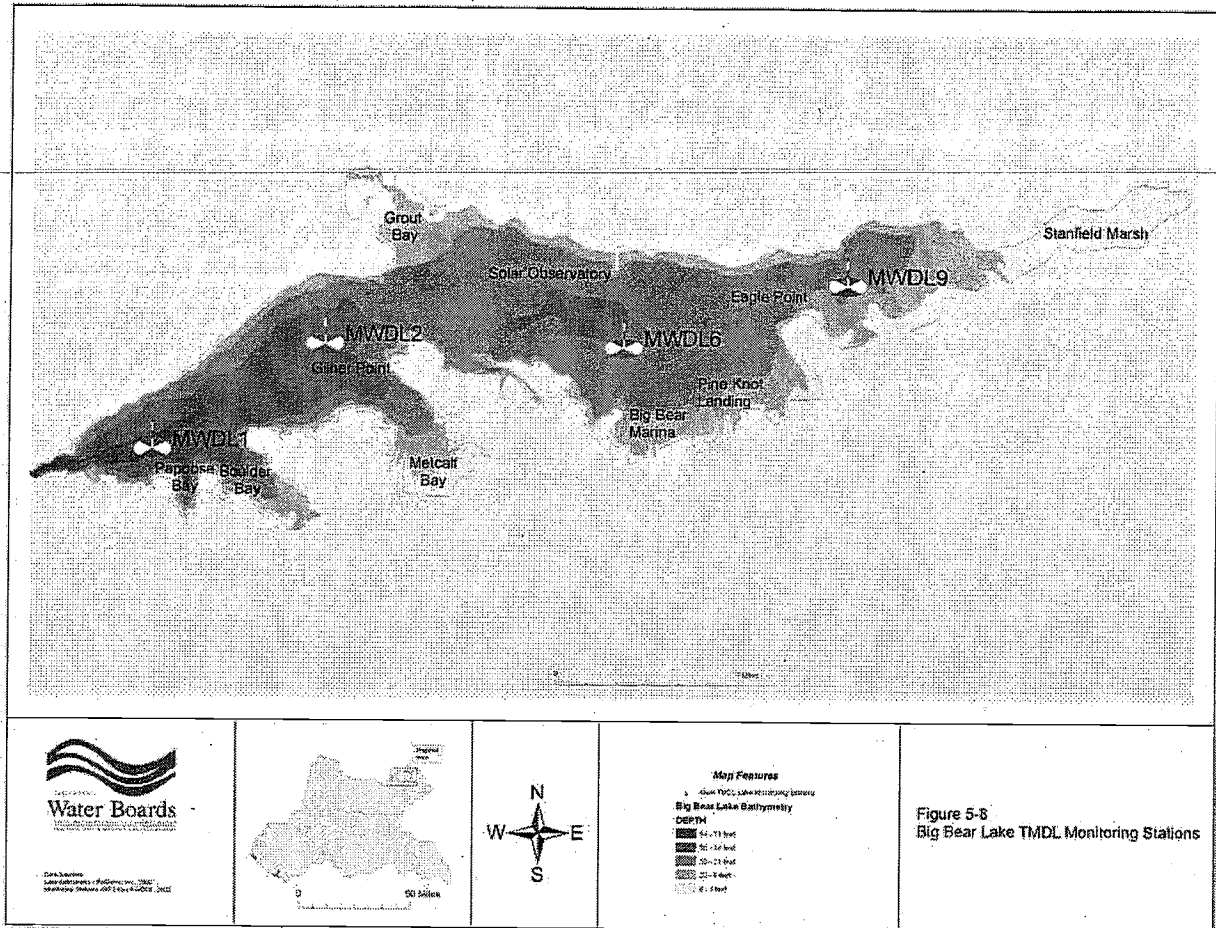

Figure 5-8 Big Bear Lake TMDL Monitoring Stations

In lieu of this coordinated monitoring plan, one or more of the parties identified above may submit a proposed individual or group monitoring plan for Regional Board approval. Any such individual or group monitoring plan is due no later than November 30, 2007 and shall be implemented upon Regional Board approval at a duly noticed public meeting. An annual report of data collected pursuant to approved individual/group plan(s), shall be submitted by February 15 of each year. The report shall summarize the data and evaluate compliance with the TMDL/WLAs/LAs and numeric targets.

Task 5: Atmospheric Deposition Determination

No later than August 31, 2008, the Regional Board, in coordination with local stakeholders, the South Coast Air Quality Management District and the California Air Resources Board, shall develop a plan and schedule for quantifying atmospheric deposition of nutrients in the Big Bear Lake watershed.

Task 6: Big Bear Lake-Lake Management Plan

No later than August 31, 2008, the US Forest Service, the State of California, Department of Transportation (Caltrans), the County of San Bernardino, San Bernardino County Flood Control District, the City of Big Bear Lake, and Big Bear Mountain Resorts, shall, as a group, submit to the Regional Board for approval a proposed Lake Management Plan for Big Bear Lake. The purpose of the plan is to identify a coordinated and comprehensive strategy for management of the lake and surrounding watershed to address restoration and protection of the lake's beneficial uses. The plan shall include the following:

- A) A proposed plan and schedule for updating the existing Big Bear Lake watershed nutrient model and the Big Bear Lake in-lake nutrient model. The plan and schedule must take into consideration additional data and information that are or will be generated from the required TMDL monitoring programs (Tasks 4.1 and 4.2, above).
- B) A proposed plan and schedule for in-lake sediment nutrient reduction for Big Bear Lake. The proposed plan shall include an evaluation of the applicability of various in-lake treatment technologies to support development of a long-term strategy for control of nutrients from the sediment. The submittal shall also contain a proposed sediment nutrient monitoring program to evaluate the effectiveness of any strategies implemented.
- C) The proposed plan shall include an evaluation of the applicability of various in-lake treatment technologies to control noxious and nuisance aquatic plants. The plan shall also include a description of the monitoring conducted and proposed to track aquatic plant diversity, coverage, and biomass. Data to be collected and analyzed shall address, at a minimum, determination of compliance with the numeric targets for macrophyte coverage and percentage of nuisance aquatic vascular plant species (see 1.A., above).

In addition, at a minimum, the proposed plan shall also address the following:

- The plan shall be based on identified and acceptable goals for lake capacity, biological resources and recreational opportunities. Acceptable goals shall be identified in coordination with the Regional Board and other responsible agencies, including the California Department of Fish and Game and the U.S. Fish and Wildlife Service.
- The plan shall include a proposed plan and schedule for the development of biocriteria for Big Bear Lake. (This is intended to complement Regional Board efforts to develop biocriteria and to signal the parties' commitment to participate substantively.)
- The plan must identify a scientifically defensible methodology for measuring changes in the capacity of the lake.
- The proposed plan shall identify recommended short and long-term strategies for control and management of sediment and dissolved and particulate nutrient inputs to the lake.
- The plan shall also integrate the beneficial use survey information required to be developed pursuant to the Regional Board's March 3, 2005, Clean Water Act Section 401 Water Quality Standards Certification for Big Bear Lake Nutrient/Sediment Remediation Project, City of Big Bear Lake, County of San Bernardino, California. The purpose of the beneficial use survey is to correlate beneficial uses of the lake with lake bottom contours. The survey is required to be conducted throughout the lake. The survey will determine the location and the quality of beneficial uses of the lake and the contours of the lake bottom where these uses occur. The survey is expected to be used in regulating future lake dredge projects to maximize the restoration and protection of the lake's beneficial uses.

The Big Bear Lake – Lake Management Plan shall be implemented upon Regional Board approval at a duly noticed public meeting. Once approved, the plan shall be reviewed and revised as necessary at least once

every three years. The review and revision shall take into account assessments of the efficacy of control/management strategies implemented and relevant requirements of new or revised TMDLs for Big Bear Lake and its watershed. An annual report summarizing the data collected for the year and evaluating compliance with the TMDL/WLAs/LAs and numeric targets shall be submitted by February 15 of each year.

~~In lieu of this coordinated plan, one or more of the parties identified above may submit a proposed individual or group Big Bear Lake – Lake Management Plan and schedule for approval by the Regional Board. Any such individual or group plan must conform to the requirements specified above and is due no later than August 31, 2008. An individual or group plan shall be implemented upon Regional Board approval at a duly noticed public meeting. An annual report summarizing the data collected for the year and evaluating compliance with the TMDL/WLAs/LAs and numeric targets shall be submitted by February 15 of each year.~~

Task 7: Review and Revision of Big Bear Lake Water Quality Standards

By December 31, 2015, the Regional Board shall:

- 7.1 Review/revise as necessary the total inorganic nitrogen and total phosphorus numeric water quality objectives for Big Bear Lake. The Regional Board shall also consider the development of narrative or numeric objectives for other indicators of impairment (e.g., chlorophyll *a*, macrophyte coverage and species composition), in lieu of or in addition to review/revision of the numeric objectives for phosphorus and nitrogen.
- 7.2 Develop biocriteria for Big Bear Lake.
- 7.3 Develop a definition for natural background sources of nutrients (and other constituents) to Big Bear Lake and its tributaries.

Given budgetary constraints, completion of these tasks are likely to require substantive contributions from interested parties.

Task 8: Review of Big Bear Lake Tributary Data

No later than December 2008, the Regional Board shall review data collected on Rathbun Creek, Summit Creek and Grout Creek to determine whether beneficial uses of these tributaries are impaired by nutrients. If the Creeks are found to be impaired by nutrients, the Regional Board shall develop a TMDL development project plan and schedule.

If these tributaries are found not to be impaired by nutrients, Regional Board shall schedule the delisting of the tributaries from the 303(d) list of impaired waters at the earliest opportunity.

Task 9: Development of TMDLs for Wet and/or Average Hydrological Conditions

No later than December 31, 2012, the Regional Board shall utilize additional water quality data and information collected pursuant to monitoring program requirements (Tasks 4 and 5) and model updates (Task 6A) to develop proposed nutrient TMDLs for Big Bear Lake for wet and/or average hydrological conditions. Completion of this task is contingent on the collection of requisite data for wet and/or average hydrological conditions.

Task 10: Review/Revision of the Big Bear Lake Nutrient TMDL for Dry Hydrological Conditions (TMDL "Re-opener")

The basis for the TMDL for Dry Hydrological Conditions, the implementation plan and schedule will be re-evaluated at least once every three years² to determine the need for modifying the allocations, numeric targets and TMDL. Regional Board staff will continue to review all data and information generated pursuant to the TMDL requirements on an ongoing basis. Based on results generated through the monitoring programs, special studies and/or modeling analyses, changes to the TMDL may be warranted. Such changes will be considered through the Basin Plan Amendment process.

The Regional Board is committed to the review of this TMDL every three years, or more frequently if warranted by these or other studies.

ATTACHMENT 50

CHAPTER 4

WATER QUALITY OBJECTIVES

INTRODUCTION

The Porter-Cologne Act defines water quality objectives as "...the limits or levels of water quality constituents or characteristics which are established for the reasonable protection of beneficial uses of water or the prevention of nuisance within a specific area" (§13050 (h)). Further, the Act directs (§13241) that:

"Each regional board shall establish such water quality objectives in water quality control plans as in its judgment will ensure the reasonable protection of beneficial uses as the prevention of nuisance; however, it is recognized that it may be possible for the quality of water to be changed to some degree without unreasonably affecting beneficial uses. Factors to be considered by a regional board in establishing water quality objectives shall include, but not necessarily be limited to, all of the following:

- (a) Past, present, and probable future beneficial uses of water.
- (b) Environmental characteristics of the hydrographic unit under consideration, including the quality of water available thereto.
- (c) Water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area.
- (d) Economic considerations.
- (e) The need for developing housing within the region.
- (f) The need to develop and use recycled water."

Two important additional factors which were also considered in setting the water quality objectives in this Plan are (1) historic and present water quality, and (2) the antidegradation policies cited in Chapter 2.

The water quality objectives in this plan supersede and replace those adopted in the 1983 Basin Plan. Perhaps the most significant difference between this and the prior Plan is the inclusion of new objectives for un-ionized ammonia and site-specific objectives for the middle Santa Ana River system for copper, cadmium, and lead.

Some of these water quality objectives refer to "controllable sources" or "controllable water quality factors." Controllable sources include both point and nonpoint source discharges, such as conventional discharges from pipes, as well as discharges from land areas or other diffuse sources. Controllable water quality factors are those characteristics of the discharge and/or the receiving water which can be controlled by

treatment or management methods. Examples of other activities which may not involve waste discharges, but which also constitute controllable water quality factors, include the percolation of storm water, transport/delivery of water via natural stream channels, and stream diversions.

The water quality objectives in this Plan are specified according to waterbody type: ocean waters; enclosed bays and estuaries; inland surface waters; and groundwaters.

The narrative water quality objectives below are arranged alphabetically. They vary in applicability and scope, reflecting the variety of beneficial uses of water that have been identified (Chapter 3). Where numerical objectives are specified, they generally represent the levels that will protect beneficial uses. However, in establishing waste discharge requirements for specific discharges, the Regional Board may find that more stringent levels are necessary to protect beneficial uses. In other cases, an objective may prohibit the discharge of specific substances, may tolerate natural or "background" levels of certain substances or characteristics but no increases over those values, or may express a limit in terms of not impacting other beneficial uses. An adverse effect or impact on a beneficial use occurs where there is an actual or threatened loss or impairment of that beneficial use.

OCEAN WATERS (Amended by Resolution No. 97-20, April 18, 1997)

Water quality objectives specified in the "Water Quality Control Plan for Ocean Waters of California" (Ocean Plan) and the "Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California" (Thermal Plan) are incorporated into this Basin Plan by reference. The provisions of the Ocean Plan and Thermal Plan apply to the ocean waters within this Region. (End of Resolution No. 97-20)

ENCLOSED BAYS AND ESTUARIES

"Enclosed bays" means indentations along the coast which enclose an area of oceanic water within distinct headlands or harbor works. "Estuaries" means waters, including coastal lagoons, located at the mouths of streams which serve as areas of mixing for fresh and ocean waters. Enclosed bays and estuaries do not include ocean waters or inland surface waters (see definition in the Inland Surface Waters section).

The objectives which are included below apply to all enclosed bays and estuaries within the region. In addition to these parameter-specific objectives, the following narrative objective shall apply:

Enclosed bay and estuarine communities and populations, including vertebrate, invertebrate, and plant species, shall not be degraded as a result of the discharge of waste. Degradation is damage to an aquatic community or population with the result that a balanced community no longer exists. A balanced community is one that is (1) diverse, (2) has the ability to sustain itself through cyclic seasonal changes, (3) includes necessary food chain species, and (4) is not dominated by pollution-tolerant

species, unless that domination is caused by physical habitat limitations. A balanced community also (5) may include historically introduced non-native species, but (6) does not include species present because best available technology has not been implemented, or (7) because site-specific objectives have been adopted, or (8) because of thermal discharges.

Algae

Excessive growth of algae and/or other aquatic plants can degrade water quality. Algal blooms sometimes occur naturally, but they are often the result of excess nutrients (*i.e.*, nitrogen, phosphorus) from waste discharges or nonpoint sources. These blooms can lead to problems with tastes, odors, color, and increased turbidity and can depress the dissolved oxygen content of the water, leading to fish kills. Floating algal scum and algal mats are also an aesthetically unpleasant nuisance.

Waste discharges shall not contribute to excessive algal growth in receiving waters.

Bacteria, Coliform

Fecal bacteria are part of the intestinal flora of warm-blooded animals. Their presence in bay and estuarine waters is an indicator of pollution. Total coliform is measured in terms of the number of coliform organisms per unit volume. Total coliform numbers can include non-fecal bacteria, so additional testing is often done to confirm the presence and numbers of fecal coliform bacterial. Water quality objectives for numbers of total and fecal coliform vary with the uses of the water, as shown below.

Bays and Estuaries

REC-1 *Fecal coliform: log mean less than 200 organisms/100 mL based on five or more samples/30 day period, and not more than 10% of the samples exceed 400 organisms/100 mL for any 30-day period.*

SHEL *Fecal coliform: median concentration not more than 14 MPN (most probable number)/100 ml and not more than 10% of samples exceed 43 mpn / 100 mL*

Chlorine, Residual

Wastewater disinfection with chlorine usually produces a chlorine residual. Chlorine and its reaction products are toxic to aquatic life.

To protect aquatic life, the chlorine residual in wastewater discharged to enclosed bays and estuaries shall not exceed 0.1 mg/L.

Color

Color in water may arise naturally, such as from minerals, plant matter or algae, or may be caused by industrial pollutants. Color is primarily an aesthetic consideration.

Waste discharges shall not result in coloration of the receiving waters which causes a nuisance or adversely affects beneficial uses. The natural color of fish, shellfish or other bay and estuarine water resources used for human consumption shall not be impaired.

Floatables

Floatables are an aesthetic nuisance as well as a substrate for algae and insect vectors.

Waste discharges shall not contain floating materials, including solids, liquids, foam or scum, which cause a nuisance or adversely affect beneficial uses.

Oil and Grease

Oil and grease can be present in water as a result of the discharge of treated wastes and the accidental or intentional dumping of wastes into sinks and storm drains. Oils and related materials have a high surface tension and are not soluble in water, therefore forming a film on the water's surface. This film can result in nuisance conditions because of odors and visual impacts. Oil and grease can coat birds and aquatic organisms, adversely affecting respiration and/or thermoregulation.

Waste discharges shall not result in deposition of oil, grease, wax or other materials in concentrations which result in a visible film or in coating objects in the water, or which cause a nuisance or adversely affect beneficial uses.

Oxygen, Dissolved

Adequate dissolved oxygen (D.O.) is vital for aquatic life. Depression of D.O. levels can lead to fish kills and odors resulting from anaerobic decomposition. Dissolved oxygen content in water is a function of water temperature and salinity.

The dissolved oxygen content of enclosed bays and estuaries shall not be depressed to levels that adversely affect beneficial uses as a result of controllable water quality factors.

pH

pH is a measure of the hydrogen ion concentration of water. pH values generally range from 0 (most acidic) to 14 (most alkaline). Many pollutants can alter the pH, raising or lowering it excessively. These extremes in pH can have adverse effects on aquatic biota and can corrode pipes and concrete. Even small changes in pH can harm aquatic biota.

The pH of bay or estuary waters shall not be raised above 8.6 or depressed below 7.0 as a result of controllable water quality factors; ambient pH levels shall not be changed more than 0.2 units.

Radioactivity

Radioactive materials shall not be present in the bay or estuarine waters of the region in concentrations which are deleterious to human, plant or animal life.

Solids, Suspended and Settleable

Settleable solids are deleterious to benthic organisms and may cause anaerobic conditions to form. Suspended solids can clog fish gills and interfere with respiration in aquatic fauna. They also screen out light, hindering photosynthesis and normal aquatic plant growth and development.

Enclosed bays and estuaries shall not contain suspended or settleable solids in amounts which cause a nuisance or adversely affect beneficial uses as a result of controllable water quality factors.

Sulfides

Sulfides are generated by many industries and from the anaerobic decomposition of organic matter. In water, sulfides can react to form hydrogen sulfide (H₂S), commonly known for its "rotten egg" odor. Sulfides in ionic form are also toxic to fish.

The dissolved sulfide content of enclosed bays and estuaries shall not be increased as a result of controllable water quality factors.

Surfactants (surface-active agents)

This group of materials includes detergents, wetting agents, and emulsifiers.

Waste discharges shall not contain concentrations of surfactants which result in foam in the course of flow or the use of the receiving water, or which adversely affect aquatic life.

Taste and Odor

Undesirable tastes and odors in water may be a nuisance and may indicate the presence of a pollutant(s).

The enclosed bays and estuaries of the region shall not contain, as a result of controllable water quality factors, taste- or odor-producing substances at concentrations which cause a nuisance or adversely affect beneficial uses. The natural taste and odor of fish, shellfish or other enclosed bay and estuarine water resources used for human consumption shall not be impaired.

Temperature

Waste discharges can cause temperature changes in the receiving waters which adversely affect the aquatic biota. Discharges most likely to cause these temperature effects are cooling tower and heat exchanger blowdown.

All bay and estuary waters shall meet the objective specified in the Thermal Plan.

Toxic Substances

Toxic substances shall not be discharged at levels that will bioaccumulate in aquatic resources to level which are harmful to human health.

The concentrations of toxic substances in the water column, sediments or biota shall not adversely affect beneficial uses.

Turbidity

Turbidity is a measure of light scattered due to particulates in water.

Increases in turbidity which result from controllable water quality factors shall comply with the following:

<u>Natural Turbidity</u>	<u>Maximum Increase</u>
0-50 NTU	20%
50-100 NTU	10 NTU
Greater than 100 NTU	10%

All enclosed bay and estuaries of the region shall be free of changes in turbidity which adversely affect beneficial uses.

INLAND SURFACE WATERS

Inland surface waters include streams, rivers, lakes, and wetlands in the Region. Ocean waters and enclosed bays and estuaries are not considered inland surface waters.

The narrative objectives which are included below apply to all inland surface waters within the region, including lakes, streams, and wetlands. In addition, specific numerical objectives are listed in Table 4-1. Where more than one objective is applicable, the stricter shall apply. In addition to these objectives, the following shall apply:

Inland surface water communities and populations, including vertebrate, invertebrate, and plant species, shall not be degraded as a result of the discharge of waste. Degradation is damage to an aquatic community or population with the result that balanced community no longer exists. A balanced community is one that is (1) diverse, (2) has the ability to sustain itself through cyclic seasonal changes, (3) includes necessary food chain species, and (4) is not dominated by pollution-tolerant species, unless that domination is caused by physical habitat limitations. A balanced community also (5) may include historically introduced non-native species, but (6) does not include species present because best available technology has not been implemented, or (7) because site-specific objectives have been adopted, or (8) because of thermal discharges.

Algae

Excessive growth of algae and/or other aquatic plants can degrade water quality. Algal blooms sometimes occur naturally, but they are often the result of excess nutrients (*i.e.*, nitrogen, phosphorous) from waste discharges or nonpoint sources. These blooms can lead to problems with tastes, odors, color, and increased turbidity and can depress the dissolved oxygen content of the water, leading to fish kills. Floating algal scum and algal mats are also an aesthetically unpleasant nuisance.

Waste discharges shall not contribute to excessive algal growth in inland surface receiving waters.

Ammonia, Un-ionized

Un-ionized ammonia (NH₃, or UIA) is toxic to fish and other aquatic organisms. In water, UIA exists in equilibrium with ammonium (NH₄⁺) and hydroxide (OH) ions. The proportions of each change as the temperature, pH, and salinity of the water change.

The 1983 Basin Plan specified an UIA objective of 0.8 mg/L for waterbodies designated **WARM**. The SWRCB directed the Regional Board to review the 0.8 mg/L objective because of concerns that it is not stringent enough to protect aquatic wildlife. The USEPA concurred that this review was necessary.

The Regional Board contracted with California State University, Fullerton to conduct a study of un-ionized ammonia in the Santa Ana River and to develop recommendations regarding the UIA objective. This study, which was conducted in 1985-87, was complemented by additional Regional Board staff analysis. The additional staff analysis focused on adjusting EPA's national criteria for **WARM** waters (published in 1984 and amended in 1992), using the recalculation procedure. With this procedure, cold and warmwater species not found in the Santa Ana Region's **WARM** designated waters were deleted from the database used to derive the national criteria, and new criteria were calculated.

Based on these analyses, this Plan specifies UIA objectives for **WARM** and **COLD** designated waterbodies in the Region. **Note:** site-specific objectives have been developed for the Santa Ana River and certain tributaries (see next page).

Acute (1-hour) UIA-N Objectives

For waterbodies designed **COLD**:

Objective = 0.822 [0.52/FT/FPH/2], where

$$\begin{array}{ll} FT = 10^{(0.03(20-T))} & 0 \leq T \leq 20^{\circ}\text{C} \\ FT = 1 & 20 \leq T \leq 30^{\circ}\text{C} \end{array}$$

$$FPH = \frac{1 + 10^{(7.4 - \text{pH})}}{1.25} \quad 6.5 \leq \text{pH} \leq 8$$

$$FPH = 1 \quad 8 \leq \text{pH} \leq 9$$

For waterbodies designated **WARM**:

Objective = $0.822[0.87/FT/FPH/2]$, where

$$FT = 10^{(0.03(20-T))} \quad 0 \leq T \leq 25^{\circ}\text{C}$$

$$FT = 0.7079 \quad 25 \leq T \leq 30^{\circ}\text{C}$$

$$FPH = \frac{1+10^{(7.4-pH)}}{1.25} \quad 6.5 \leq pH \leq 8$$

$$FPH = 1 \quad 8 \leq pH \leq 9$$

Chronic (4-day) UIA-N Objectives

For waterbodies designated **COLD**:

Objective = $0.822[0.52/FT/FPH/RATIO]$, where

$$FT = 10^{(0.03(20-T))} \quad 0 \leq T \leq 15^{\circ}\text{C}$$

$$FT = 1.4125 \quad 15 \leq T \leq 30^{\circ}\text{C}$$

$$FPH = \frac{1+10^{(7.4-pH)}}{1.25} \quad 6.5 \leq pH \leq 8$$

$$FPH = 1 \quad 8 \leq pH \leq 9$$

$$RATIO = \frac{24[10^{(7.7-pH)}]}{1+10^{(7.4-pH)}} \quad 6.5 \leq pH \leq 7.7$$

$$RATIO = 13.5 \quad 7.7 \leq pH \leq 9$$

For waterbodies designated **WARM**:

Objective = $0.822[0.87/FT/FPH/RATIO]$, where

$$FT = 10^{(0.03(20-T))} \quad 0 \leq T \leq 20^{\circ}\text{C}$$

$$FT = 1 \quad 20 \leq T \leq 30^{\circ}\text{C}$$

$$FPH = \frac{1+10^{(7.4-pH)}}{1.25} \quad 6.5 \leq pH \leq 8$$

$$FPH = 1 \quad 8 \leq pH \leq 9$$

$$RATIO = \frac{24[10^{(7.7-pH)}]}{1+10^{(7.4-pH)}} \quad 6.5 \leq pH \leq 7.7$$

$$RATIO = 13.5 \quad 7.7 \leq pH \leq 9$$

Calculated numerical UIA-N objectives as well as corresponding total ammonia nitrogen concentration for various pH and temperature conditions are shown in Tables

4-2 and 4-3. Table 4-4 lists the above equations in a form that can be entered into a computer or calculator program.

Site-specific Un-ionized Ammonia Objective for the Santa Ana River System

In addition to the un-ionized ammonia (UIA) objectives specified above, this Plan includes a chronic (4-day) site-specific UIA objective for the middle Santa Ana River, Chino Creek, Mill Creek (Prado Area), Temescal Creek, and San Timoteo Creek. This site-specific objective is based on carefully controlled chronic toxicity tests on Santa Ana River water conducted as part of the Santa Ana River Use-Attainability Analysis Study. The Santa Ana River water was spiked with UIA concentrations ranging from 0.0 (control) to 1.0 mg/L. The No Observed Effect Level (NOEL) was found to be at a UIA concentration of 0.24 mg/L (or 0.19 mg/L as UIA-nitrogen). Using a 50% safety factor, the UIA objective developed is 0.12 mg/L (or 0.098 mg/L UIA-nitrogen).

To prevent chronic toxicity to aquatic life in the Santa Ana River, Reaches 2, 3, and 4, Chino Creek, Mill Creek (Prado Area), Temescal Creek and San Timoteo Creek, discharges to these waterbodies shall not cause the concentration of un-ionized ammonia (as nitrogen) to exceed 0.098 mg/L) (NH₃-N) as a 4-day average.

Bacteria, Coliform

Fecal bacteria are part of the intestinal flora of warm-blooded animals. Their presence in surface waters is an indicator of pollution. Total coliform is measured in terms of the number of coliform organisms per unit volume. Total coliform numbers can include non-fecal bacteria, so additional testing is often done to confirm the presence and numbers of fecal coliform bacteria. Water quality objectives for numbers of total and fecal coliform vary with the uses of the water, as shown below.

Lakes and Streams

MUN *Total coliform: less than 100 organisms/100 mL*

REC-1 *Fecal coliform: log mean less than 200 organisms/100 mL based on five or more samples/30 day period, and not more than 10% of the samples exceed 400 organisms/100 mL for any 30-day period*

REC-2 *Fecal coliform: average less than 2000 organisms/100 mL and not more than 10% of samples exceed 4000 organisms/100 mL for any 30-day period*

Boron

Boron is not considered a problem in drinking water supplies until concentrations of 20-30 mg/L are reached. In irrigation, boron is an essential element. However, boron concentrations in excess of 0.75 mg/L may be deleterious to certain crops, particularly citrus. The maximum safe concentration of even the most tolerant plants is about 4.0mg/L of boron.

Boron concentrations shall not exceed 0.75 mg/L in inland surface waters of the region as a result of controllable water quality factors.

Chemical Oxygen Demand (COD)

COD is a measure of the total amount of oxidizable material present in a sample, including stable organic materials which are not measured by the BOD test.

Waste discharges shall not result in increases in COD levels in inland surface waters which exceed the values shown in Table 4-1 or which adversely affect beneficial uses.

Chloride

Excess chloride concentrations lead primarily to economic damage rather than public health hazards. Chlorides are considered to be among the most troublesome anions in water used for industrial or irrigation purposes since they significantly affect the corrosion rate of steel and aluminum and can be toxic to plants. A safe value for irrigation is considered to be less than 175 mg/L of chloride. Excess chlorides affect the taste of potable water, so drinking water standards are generally based on potability rather than on health. The secondary drinking water standard for chloride is 500 mg/L.

The chloride objectives listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors.

Chlorine, Residual

Wastewater disinfection with chlorine usually produces a chlorine residual. Chlorine and its reaction products are toxic to aquatic life.

To protect aquatic life, the chlorine residual in wastewater discharged to inland surface waters shall not exceed 0.1 mg/L.

Color

Color in water may arise naturally, such as from minerals, plant matter, or algae, or may be caused by industrial pollutants. Color is primarily an aesthetic consideration, although it can discolor clothes and food. The secondary drinking water standard for color is 15 color units.

Waste discharges shall not result in coloration of the receiving waters which causes a nuisance or adversely affect beneficial uses. The natural color of fish, shellfish or other inland surface water resources used for human consumption shall not be impaired.

Dissolved Solids, Total (Total Filtrable Residue)

The department of Health Services recommends that the concentration of total dissolved solids (TDS) in drinking water be limited to 1000 mg/L (secondary drinking water standard) due to taste considerations. For most irrigation uses, water should have a TDS concentration under 700mg/L. Quality-related consumer cost analyses

have indicated that a benefit to consumers exist if water is supplied at or below 500mg/L TDS.

The dissolved mineral content of the waters of the region, as measured by the total dissolved solids test ("Standard Methods for the Examination of Water and Wastewater, 16th Ed.," 1985: 209B (180°C), p. 95), shall not exceed the specific objectives listed in Table 4-1 as a result of controllable water quality factors.

Filtrable Residue, Total

See Dissolved Solids, Total

Floatables

Floatables are an aesthetic nuisance as well as a substrate for algae and insect vectors.

Waste discharges shall not contain floating materials, including solids, liquids, foam or scum, which cause a nuisance or adversely affect beneficial uses.

Fluoride

Fluoride in water supply used for industrial or irrigation purposes has certain detrimental effects. Fluoride in optimum concentrations in water supply (concentrations dependent upon the mean annual air temperature) is considered beneficial for preventing dental caries, but concentrations above approximately 1 mg/L, or its equivalent at a given temperature, are considered likely to increase the risk of occurrence of dental fluorosis.

*Fluoride concentrations shall not exceed values specified in the table below in inland surface waters designated **MUN** as a result of controllable water quality factors.*

Annual Average of Maximum Optimum Fluoride

<u>Daily Air Temperature (°C)</u>	<u>Concentration (mg/L)</u>
12.0 and below	1.2
12.1 to 14.6	1.1
14.7 to 17.6	1.0
17.7 to 21.4	0.9
21.5 to 26.2	0.8
26.3 to 32.5	0.7

Hardness (as CaCO₃)

The major detrimental effect of hardness is economic. Any concentration (reported as mg/L CaCO₃) greater than 100mg/L results in the increased use of soap, scale buildup in utensils, in domestic uses, and in plumbing. Hardness in industrial cooling waters is generally objectionable above 50mg/L.

The objectives listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors. If no hardness objective is listed in Table 4-1, the hardness of

receiving waters used for municipal supply (MUN) shall not be increased as a result of waste discharges to levels that adversely affect beneficial uses.

Inorganic Nitrogen, Total

see Nitrogen, Total Inorganic

Metals

Metals can be toxic to human and animal life.

In 1990, the Environmental Protection Agency (EPA) placed the Santa Ana River, reaches 2, 3, and 4, and Chino Creek on the §304(1) list of "Waters Not Meeting Applicable Water Quality Standards" based on its review of data on certain metals in POTW discharges to the River.

The Santa Ana River dischargers and the Regional Board disagreed with and objected to EPA's §304(1) designation. To demonstrate whether or not the §304(1) designation is correct and what effects, if any, heavy metal levels may have on aquatic life in the Region, the Santa Ana River Dischargers Association and the Santa Ana Watershed Project Authority agreed to conduct a Use-Attainability Analysis (UAA).

The purpose of a Use-Attainability Analysis is to evaluate the "physical, biological, chemical, and hydrological conditions of a river to determine what specific beneficial uses the waterbody can support." If local conditions preclude full attainment of an aquatic life beneficial use for reasons unrelated to water quality, federal and state authorities may allow variances from the generic water quality criteria.

The UAA began in February 1991 and concluded in March 1992. It provided detailed information on chemical, biological, and hydrologic conditions in the middle Santa Ana River aquatic system. Conclusions and recommendations were presented to the Board in June 1992. The information presented is reflected in the Santa Ana River discussion in Chapter 1 and in the new **LWRM** Beneficial Use designation (Chapter 3). Data provided by the UAA was also used to support the adoption of site-specific objectives for three metals, cadmium (Cd), copper (Cu), and lead (Pb) for the Santa Ana River (Reaches 2, 3, and 4) and the perennial portions of some tributaries (including Chino Creek, Cucamonga/Mill Creek, Temescal Creek, and creeks in the Riverside Narrows area).

In adopting these SSOs the Regional Board found (RWQCB Resolution No. 94-1) that:

- a. The Site-Specific Water Quality Objectives (SSOs) will protect the beneficial uses of the Santa Ana River.
- b. The SSOs are conservative.
- c. The SSOs, which represent higher quality than presently exists, will not result in degradation of water quality.

- d. Existing levels of cadmium, copper, and lead in the Santa Ana River do not contribute to toxicity in the Santa Ana River.

The toxicity of these metals varies with water hardness. No fixed hardness value is assumed; objectives are calculated using the hardness of the collected sample.

The following equations represent the SSOs which apply to these waterbodies. These SSOs are expressed as the dissolved form of the metals.

SSO for cadmium:

$$\text{Cd SSO} = 0.85[e^{(0.7852*\ln(\text{TH})-3.490)}]$$

SSO for Copper

$$\text{Cu SSO} = 0.85[e^{(0.8545*\ln(\text{TH})-1.465)}]$$

SSO for lead

$$\text{Pb SSO} = 0.25 [e^{(1.237*\ln(\text{TH})-3.958)}]$$

where TH is the total hardness (as CaCO_3) in mg/L.

The SSOs for cadmium and copper are simply the hardness-dependent formulas for calculating the objective (national criteria), corrected by the dissolved-to-total (metal) ratio. The SSO for lead is the recalculated* hardness-dependant formula, corrected by the dissolved-to-total ratio.

*Recalculation for lead was carried out by EPA-Region IX, using the lowest genus mean acute value (GMAV) as the final acute value (FAV) and an acute-to chronic ratio (ACR) of 51.29, resulting in a final chronic value (FCV) of 2.78 and the SSO formula already shown.

The Table below shows the site-specific objectives for cadmium, copper, and lead that would apply to a water sample with 200 mg/L total hardness (as CaCO₃).

<u>Metal</u>	<u>Calculated WQO</u>	<u>Recalculated Value</u>	<u>EPA</u>	
			<u>Correction Factor</u>	<u>SSO</u>
Cd	2.0	NA	0.85	1.7
Cu	21.4	NA	0.85	18.2
Pb	7.7	16.2	0.25	4.1

Toxicity testing performed as part of the Santa Ana River Use-Attainability Analysis (UAA) has demonstrated that the levels of dissolved metal shown below are safe and non-toxic in Santa Ana River water.

Cadmium	4 µg/L
Copper	37 µg/L
Lead	28 µg/L

There is also evidence that levels as much as 100% higher than those shown above do not result in chronic toxicity.

Methylene Blue-Activated Substances (MBAS)

The MBAS test is sensitive to the presence of detergents (see surfactants). Positive results may indicate the presence of wastewater. The secondary drinking water standard for MBAS is 0.05 mg/L.

*MBAS concentrations shall not exceed 0.05mg/L in inland surface waters designated **MUN** as a result of controllable water quality factors.*

Nitrate

High nitrate concentrations in domestic water supplies can be toxic to human life. Infants are particularly susceptible and may develop methemoglobinemia (blue baby syndrome). The primary drinking water standard for nitrate (as NO₃) is 45 mg/L or 10 mg/L (as N) in inland surface waters designated MUN as a result of controllable water quality factors.

*Nitrate-nitrogen concentrations shall not exceed 45 mg/L (as NO₃) or 10 mg/L (as N) in inland surface waters designated **MUN** as a result of controllable water quality factors.*

Nitrogen, Total Inorganic

The objectives listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors.

Oil and Grease

Oil and grease can be present in water as a result of the discharge of treated wastes and the accidental or intentional dumping of wastes into sinks and storm drains. Oils and related materials have a high surface tension and are not soluble in water, therefore forming a film on the water's surface. This film can result in nuisance conditions because of odors and visual impacts. Oil and grease can coat birds and aquatic organisms, adversely affecting respiration and/or thermoregulation.

Waste discharges shall not result in deposition of oil, grease, wax, or other material in concentrations which result in a visible film or in coating objects in the water, or which cause a nuisance or adversely affect beneficial uses.

Oxygen, Dissolved

Adequate dissolved oxygen (D.O.) is vital for aquatic life. Depression of D.O. levels can lead to fish kills and odors resulting from anaerobic decomposition. Dissolved oxygen content in water is a function of water temperature and salinity.

*The dissolved oxygen content of surface waters shall not be depressed below 5mg/L for waters designated **WARM**, or 6mg/L for waters designated **COLD**, as a result of controllable water quality factors. In addition, waste discharges shall not cause the median dissolved oxygen concentration to fall below 85% of saturation or the 95th percentile concentration or fall below 75% of saturation within a 30-day period.*

pH

pH is a measure of the hydrogen ion concentration of water. pH values generally range from 0 (most acidic) to 14 (most alkaline). Many pollutants can alter the pH, raising or lowering it excessively. These extremes in pH can have adverse effects on aquatic biota and can corrode pipes and concrete. Even small changes in pH can harm aquatic biota.

The pH of inland surface waters shall not be raised above 8.5 or depressed below 6.5 as a result of controllable water quality factors.

Radioactivity

*Radioactivity materials shall not be present in the waters of the region in concentrations which are deleterious to human, plant or animal life. Waters designated **MUN** shall meet the limits specified in the California Code of Regulations, Title 22, and listed here:*

Combined Radium-226 and Radium-228	5	pCi/L
Gross Alpha particle activity	15	pCi/L
Tritium	20,000	pCi/L
Strontium-90	8	pCi/L
Gross Beta particle activity	50	pCi/L
Uranium	20	pCi/L

Sodium

The presence of sodium in drinking water may be harmful to persons suffering from cardiac, renal, and circulatory diseases. It can contribute to taste effects, with the taste threshold depending on the specific sodium salt. Excess concentrations of sodium in irrigation water reduce soil permeability to water and air. The deterioration of soil quality because of the presence of sodium in irrigation water is cumulative and is accelerated by poor drainage.

The sodium objectives listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors.

Solids, Suspended and Settleable

Settleable solids are deleterious to benthic organisms and may cause anaerobic conditions to form. Suspended solids can clog fish gill and interfere with respiration in aquatic fauna. They also screen out light, hindering photosynthesis and normal aquatic plant growth and development.

Inland surface waters shall not contain suspended or settleable solids in amounts which cause a nuisance or adversely affect beneficial uses as a result of controllable water quality factors.

Sulfate

Excessive sulfate, particularly magnesium sulfate ($MgSO_4$) in potable waters can lead to laxative effects; but this effect is temporary. There is some taste effect from magnesium sulfate in the range of 400-600 mg/L as $MgSO_4$. The secondary drinking water standard for sulfate is 500 mg/L. Sulfate concentrations in waters native to this region are normally low, less than 40 mg/L, but imported Colorado River water contains approximately 300 mg/L of sulfate.

The objectives listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors.

Sulfides

Sulfides are generated by many industries and from the anaerobic decomposition of organic matter. In water, sulfides can react to form hydrogen sulfide (H_2S), commonly known for its "rotten egg" odor. Sulfides in ionic form are also toxic to fish.

The dissolved sulfide content of inland surface waters shall not be increased as a result of controllable water quality factors.

Surfactants (surface-active agents)

This group of materials includes detergents, wetting agents, and emulsifiers. See also Methylene Blue-Activated Substances (MBAS).

Waste discharges shall not contain concentrations of surfactants which result in foam in the course of flow or use of the receiving water, or which adversely affect aquatic life.

Taste and Odor

Undesirable tastes and odors in water may be a nuisance and may indicate the presence of a pollutant(s). The secondary drinking water standard for odor (threshold) is about 3 odor units.

The inland surface waters of the region shall not contain, as a result of controllable water quality factors, taste- or odor-producing substances at concentrations which cause a nuisance or adversely affect beneficial uses. The natural taste and odor of fish, shellfish or other regional inland surface water resources used for human consumption shall not be impaired.

Temperature

Waste discharges can cause temperature changes in the receiving waters which adversely affect the aquatic biota. Discharges most likely to cause these temperature effects are cooling tower and heat exchanger blowdown.

*The natural receiving water temperature of inland surface waters shall not be altered unless it can be demonstrated to the satisfaction of the Regional Board that such alteration in temperature does not adversely affect beneficial uses. The temperature of waters designated **COLD** shall not be increased by more than 5°F as a result of controllable water quality factors. The temperature of waters designated **WARM** shall not be raised above 90°F June through October or above 78°F during the rest of the year as a result of controllable water quality factors. Lake temperatures shall not be raised more than 4°F above established normal values as a result of controllable water quality factors.*

Total Dissolved Solids

See Dissolved Solids, Total

Total Filtrable Residue

See Dissolved Solids, Total

Total Inorganic Nitrogen

See Nitrogen, Total Inorganic

Toxic Substances

Toxic substances shall not be discharged at levels that will bioaccumulate in aquatic resources to levels which are harmful to human health.

The concentrations of contaminants in waters which are existing or potential sources of drinking water shall not occur at levels that are harmful to human health.

The concentrations of toxic pollutants in the water column, sediments or biota shall not adversely affect beneficial uses.

Turbidity

Turbidity is a measure of light scattered due to particulates in water. The secondary drinking water standard for turbidity is 5 NTU (nephelometric turbidity units).

Increases in turbidity which result from controllable water quality factors shall comply with the following:

<u>Natural Turbidity</u>	<u>Maximum Increase</u>
0-5 NTU	20%
50-100 NTU	10 NTU
Greater than 100 NTU	10%

All inland surface waters of the region shall be free of changes in turbidity which adversely affect beneficial uses.

GROUNDWATERS

The narrative objectives that are included below apply to all groundwaters, as noted. In addition, specific numerical objectives are listed in Table 4-1. With the exception of the "maximum benefit" objective identified in this Table (see further discussion below and in Chapter 5), where more than one objective is applicable, the stricter shall apply.

Arsenic

*Arsenic concentrations shall not exceed 0.05 mg/L in groundwater designated **MUN** as a result of controllable water quality factors.*

Bacteria, Coliform

Fecal bacteria are part of the intestinal flora of warm-blooded animals. Their presence in groundwater is an indicator of pollution. Total coliform is measured in terms of the number of coliform organisms per unit volume. Total coliform numbers can include non-fecal bacteria, so additional testing is often done to confirm the presence and numbers of fecal coliform bacteria. Water quality objectives for numbers of total fecal coliform vary with the uses of the water, as shown below.

*Total coliform numbers shall not exceed 2.2 organism/100 mL median over any seven-day period in groundwaters designated **MUN** as a result of controllable water quality factors.*

Barium

*Barium concentrations shall not exceed 1.0mg/L in groundwaters designated **MUN** as a result of controllable water quality factors.*

Boron

Boron is not considered a problem in drinking water supplies until concentrations of 20-30 mg/L are reached. In irrigation, boron is an essential element. However, boron concentrations in excess of 0.75 mg/L may be deleterious to certain crops, particularly citrus. The maximum safe concentration of even the most tolerant plants is about 4.0 mg/L of boron.

Boron concentrations shall not exceed 0.75 mg/L in groundwaters of the region as a result of controllable water quality factors.

Chloride

Excess chloride concentrations lead primarily to economic damage rather than public health hazards. Chlorides are considered to be among the most troublesome anion in water used for industrial or irrigation purposes since they significantly affect the corrosion rate of steel and aluminum and can be toxic to plants. A safe value for irrigation is considered to be less than 175 mg/L of chloride. Excess chlorides affect the taste of potable water, so drinking water standards are generally based on potability rather than on health. The secondary maximum contaminant level range - upper for chloride is 500 mg/L (CCR, Division 4, Chapter 15, Article 16, § 64449).

*Chloride concentrations shall not exceed 500 mg/L in groundwaters of the region designated **MUN** as a result of controllable water quality factors.*

Color

Color in water may arise naturally, such as from minerals, plant matter or algae, or may be caused by industrial pollutants. Color is primarily an aesthetic consideration, although it can discolor clothes and food. The secondary drinking water standard for color is 15 color units.

Waste discharges shall not result in coloration of the receiving waters which causes a nuisance or adversely affects beneficial uses.

Cyanide

*Cyanide concentrations shall not exceed 0.2mg/L in groundwaters designated **MUN** as a result of controllable water quality factors.*

Dissolved Solids, Total (Total Filtrable Residue)

The Department of Health Services recommends that the concentration of total dissolved solids (TDS) in drinking water be limited to 500 mg/L (secondary maximum contaminant level) (CCR, Division 4, Chapter 15, Article 16, § 64449), due to taste considerations. For most irrigation uses, water should have a TDS concentration under 700 mg/L. Quality-related consumer cost analyses have indicated that a benefit to consumers exists if water is supplied at or below 500 mg/L TDS².

The dissolved mineral content of the waters of the region, as measured by the total dissolved solids test ("Standard Methods for the Examination of Water and Wastewater, 20th Ed.," 1998: 2540C (180°C), p.2-56), shall not exceed the specific objectives listed in Table 4-1 as a result of controllable water quality factors. (See also discussion of management zone TDS and nitrate nitrogen water quality objectives).

Filtrable Residue, Total

See Dissolved Solids, Total

Fluoride

Fluoride in water supply used for industrial or irrigation purposes has certain detrimental effects. Fluoride in optimum concentrations in water supply (concentration dependent upon the mean annual air temperature) is considered beneficial for preventing dental caries, but concentrations above approximately 1 mg/L, or its equivalent at a given temperature, are considered likely to increase the risk of occurrence of dental fluorosis.

*Fluoride concentrations shall not exceed 1.0 mg/L in groundwaters designated **MUN** as a result of controllable water quality factors.*

Hardness (as CaCO₃)

The major detrimental effect of hardness is economic. Any concentration (reported as mg/L CaCO₃) greater than 100mg/L results in the increased use of soap, scale buildup in utensils in domestic uses, and in plumbing. Hardness in industrial cooling waters is generally objectionable above 50 mg/L.

*The hardness of receiving waters used for municipal supply (**MUN**) shall not be increased as a result of waste discharges to levels that adversely affect beneficial uses.*

Metals

Metals can be toxic to human and animal life.

*Metals concentrations shall not exceed the values listed below in groundwaters designated **MUN** as a result of controllable water quality factors.*

² These TDS values are noted for information purposes only. For some management zones, the historic ambient quality, on which the TDS objectives are largely based (see also discussion of maximum benefit objectives for specific management zones), exceeds these recommended levels.

<u>Metal</u>	<u>Concentration (mg/L)</u>
Cadmium	0.01
Chromium	0.05
Cobalt	0.2
Copper	1.0
Iron	0.3
Lead	0.05
Manganese	0.05
Mercury	0.002
Selenium	0.01
Silver	0.05

Methylene Blue-Activated Substances (MBAS)

The MBAS test is sensitive to the presence of detergents (see surfactants in inland surface waters discussion). Positive results may indicate the presence of wastewater. The secondary drinking water standard for MBAS is 0.05 mg/L.

*MBAS concentrations shall not exceed 0.05 mg/L in groundwaters designated **MUN** as a result of controllable water quality factors.*

Nitrate

High nitrate concentrations in domestic water supplies can be toxic to human life. Infants are particularly susceptible and may develop methemoglobinemia (blue baby syndrome). The primary drinking water standard for nitrate (as NO₃) is 45 mg/L or 10 mg/L (as N).

Nitrate-nitrogen concentrations listed in Table 4-1 shall not be exceeded as a result of controllable water quality factors. (See also discussion of management zone TDS and nitrate nitrogen water quality objectives below).

Oil and Grease

Oil and grease can be present in water as a result of the discharge of treated wastes and the accidental or intentional dumping of wastes into sinks and storm drains. Oils and related materials have a high surface tension and are not soluble in water, therefore forming a film on the water's surface. This film can result in nuisance conditions because of odors and visual impacts.

Waste discharges shall not result in deposition of oil, grease, wax or other materials in concentrations which cause a nuisance or adversely affect beneficial uses.

pH

pH is a measure of the hydrogen ion concentration of water. pH values generally range from 0 (most acidic) to 14 (most alkaline). Many pollutants can alter the pH,

raising or lowering it excessively. These extremes in pH can corrode pipes and concrete.

The pH of groundwater shall not be raised above 9 or depressed below 6 as a result of controllable water quality factors.

Radioactivity

*Radioactive materials shall not be present in the waters of the region in concentrations which are deleterious to human, plant or animal life. Groundwaters designated **MUN** shall meet the limits specified in the California Code of Regulations, Title 22, and listed here:*

<i>Combined Radium-226 and Radium-228</i>	5	pCi/L
<i>Gross Alpha particle activity</i>	15	pCi/L
<i>Tritium</i>	20,000	pCi/L
<i>Strontium-90</i>	8	pCi/L
<i>Gross Beta particle activity</i>	50	pCi/L
<i>Uranium</i>	20	pCi/L

Sodium

The presence of sodium in drinking water may be harmful to persons suffering from cardiac, renal and circulatory diseases. It can contribute to taste effects, with the taste threshold depending on the specific sodium salt (US Geological Survey, Resources Agency of California – State Water Resources Control Board). Excess concentrations of sodium in irrigation water reduce soil permeability to water and air. The deterioration of soil quality because of the presence of sodium in irrigation water is cumulative and is accelerated by poor drainage (California State Water Resources Control Board).

The California Department of Health Services and the U.S. Environmental Protection Agency have not provided a limit on the concentration of sodium in drinking water. Sodium concentrations shall not exceed 180 mg/L in groundwaters designated MUN as a result of controllable water quality factors.

Groundwaters designated AGR shall not exceed a sodium absorption ration (SAR³) of 9 as a result of controllable water quality factors.

³ Sodium absorption ratio (SAR) =
$$\frac{Na}{\left[\frac{1}{2}(Ca + Mg) \right]^{1/2}}$$

where Sodium (Na), Calcium (Ca) and Magnesium (Mg) are concentrations in milliequivalents per liter

Sulfate

Excessive sulfate, particularly magnesium sulfate ($MgSO_4$) in potable waters can lead to laxative effects, but this effect is temporary. There is some taste effect from magnesium sulfate in the range of 400-600mg/L as $MgSO_4$. The secondary drinking water standard for sulfate is 500mg/L (CCR, Division 4, Chapter 15, Article 16, §64449). Sulfate concentrations in waters native to this region are normally low, less than 40mg/L, but imported Colorado River water contains approximately 300mg/L of sulfate.

Sulfate concentrations shall not exceed 500 mg/L in groundwaters of the region designated MUN as a result of controllable water quality factors.

Taste and Odor

Undesirable tastes and odors in water may be a nuisance and may indicate the presence of a pollutant(s). The secondary drinking water standard for odor (threshold) is 3 odor units.

The groundwaters of the region shall not contain, as a result of controllable water quality factors, taste- or odor-producing substances at concentrations which cause a nuisance or adversely affect beneficial uses.

Total Dissolved Solids

See Dissolved Solids, Total

Total Filtrable Residue

See Dissolved Solids, Total

Total Inorganic Nitrogen

See Nitrogen, Total Inorganic

Toxic Substances

All waters of the region shall be maintained free of substances in concentrations which are toxic, or that produce detrimental physiological responses in human, plant, animal or aquatic life.

Management Zone TDS and Nitrate-nitrogen Water Quality Objectives (Amended by Resolution No. R8-2004-0001, January 22, 2004)

The TDS and nitrate-nitrogen objectives specified in the 1975 and 1984 Basin Plans, and initially in this 1995 Basin Plan, were based on an evaluation of groundwater samples from the five year period 1968 through 1972. This period represented ambient quality at the time of preparation of the 1975 Basin Plan. As part of the 2004 update of the TDS/Nitrogen management plan in the Basin Plan, historical ambient quality was reviewed using additional data and rigorous statistical procedures. This update also included characterization of current water quality. A

comprehensive description of the methodology employed is published in the "Final Technical Memorandum for Phase 2A of the Nitrogen-TDS Study" (Wildermuth Environmental Inc., July 2000). This effort, coupled with "maximum benefit" demonstrations by certain agencies in the watershed (see further discussion below and in Chapter 5), culminated in the adoption of the TDS and nitrate-nitrogen objectives specified in Table 4-1.

For the most part, the TDS and nitrate-nitrogen water quality objectives for each management zone are based on historical concentrations of TDS and nitrate-nitrogen from 1954 through 1973 and are referred to herein as the "antidegradation" objectives. This period brackets 1968, when the State Board adopted the state's antidegradation policy in Resolution No. 68-16, "Policy with Respect to Maintaining High Quality Waters". This Resolution establishes a benchmark for assessing and considering authorization of degradation of water quality. The 20-year period was selected in order to ensure that at least 3 data points in each management zone would be available to calculate historical ambient quality. In general, the following steps were taken to calculate the TDS and nitrate objectives:

- a. Annual average TDS and nitrate-nitrogen data from 1954 – 1973 for each well in a management zone were compiled;
- b. For each well, the data were statistically analyzed. The mean plus "t" (Student's t) times the standard error of the mean was calculated;
- c. A rectangular grid across all management zones was overlaid. Groundwater storage within each grid was computed; and,
- d. The volume-weighted TDS and nitrate-nitrogen concentration for each management zone was computed. These concentrations are the calculated historical ambient quality for each zone.⁴

These volume-weighted TDS and nitrate-nitrogen concentrations for each management zone were typically identified as the appropriate objectives. However, it is important to note that if the calculated nitrate-nitrogen concentration exceeded 10 mg/L, the nitrate-nitrogen objective was set to 10 mg/L to be consistent with the primary drinking water standard, or to current ambient quality if less than 10 mg/L.

Finally, in some cases, certain agencies proposed alternative, less stringent TDS and nitrate-nitrogen objectives for specific management zones, based on additional consideration of antidegradation requirements and the factors specified in Water Code Section 13241 (see below and Chapter 5). Table 4-1 includes both the historical ambient quality TDS and nitrate-nitrogen objectives (the "antidegradation" objectives) and the objectives based on this additional consideration (the "maximum benefit"

⁴ In limited cases, data for ammonia-nitrogen and nitrite-nitrogen as well as nitrate-nitrogen were available and included in the analysis. The ammonia-nitrogen and nitrite-nitrogen values were insignificant. The objectives are thus expressed as nitrate-nitrogen, even where ammonia-nitrogen and nitrite-nitrogen data were included in the analysis.

objectives) for specific management zones. Chapter 5 specifies detailed requirements noticed Public Hearing, the Regional Board finds that "maximum benefit" is not being demonstrated, then the "antidegradation" objectives apply for regulatory purposes.

THE SANTA ANA RIVER

Setting objectives for the flowing portions of the Santa Ana River is a significant feature of this Basin Plan. The River provides water for recreation and for aquatic and wildlife habitat. River flows are a significant source of groundwater recharges in lower basin, which provides domestic supplies for more than two million people. These flows account for about 70% of the total recharge.

The dividing line between reaches 2 and 3 of the River, and between the upper and lower Santa Ana Basins, is Prado Dam, a flood control facility built and operated by the U.S. Army Corps of Engineers. The dam includes a subsurface groundwater barrier, and as a result all ground and surface waters from the upper basin are forced to pass through the dam (or over the spillway). For this reason, it is an ideal place to measure flows and monitor water quality.

The Prado Settlement, a stipulated court judgement (*Orange County Water District vs. City of Chino, et al*), which requires that a certain minimum amount of water be released each year from the upper basin, is overseen by the Santa Ana River Watermaster. The U.S. Geologic Survey (USGS) operates a permanent continuous monitoring station immediately below Prado Dam, and the data collected there are utilized by the Watermaster. Orange County Water District (OCWD) samples the river monthly at the USGS gage and determines the water quality. Compliance with the objective for reaches 2 and 3 is monitored by the Regional Board, using the data and information available from the USGS gage and these sources, plus the data from its own specific sampling programs. (see Chapter 6).

The quality of the Santa Ana River is a function of the quantity and quality of the various components of the flows. The two major components of total flow are storm flow and base flow. Storm flow is the water which results directly from rainfall (surface runoff) in the upper basin; it also includes the stormwater runoff from the San Jacinto Basin which may reach the River via Temescal Creek. Most storms occur during the winter rainy season (December through April). Base flow is composed of wastewater discharges, rising groundwater, and nonpoint source discharges. Wastewater discharges are the treated sewage effluents discharged by municipalities to the river and its tributaries. Rising groundwater occurs at a number of locations along the River, including the San Jacinto Fault, Riverside Narrows, and in or near the Prado flood Control Basin. Nonpoint source discharges include uncontrolled runoff from agricultural and urban areas which is not related to storm flows.

Nontributary flow is a third element of total flow. It is generally imported water released in the upper basin, for recharge in the lower basin (Santa Ana Forebay).

The Santa Ana River Watermaster calculates the amount and quality of total flow for each water year (October 1 to September 30). The Watermaster's Annual Report is used to determine compliance with the stipulated judgement referred to earlier, which set quality and quantity limits on the river. The Watermaster's report presents summary data compiled from the continuous monitoring of flow in cfs (cubic feet per second) and salinity as EC (electrical conductivity) at the USGS Prado Gaging Station. The Watermaster's annual determination of total flow quality will be used to determine compliance with the total flow objective in this Plan. In years of normal rainfall, most of the total flow of the river is percolated in the Santa Ana Forebay, and directly affects the quality of the groundwater. For that reason, compliance with the total dissolved solids (TDS) water quality objective for Reach 2 will be based on the five-year moving average of the annual TDS content of total flow. Use of this moving average allows the effects of wet and dry years to be smoothed out over the five-year period.

As was noted earlier, the three components of base flow in the river are wastewater, rising water, and nonpoint source discharges. These three components are present in varying amounts throughout the year, and the contributions and quality of each can be affected by the regulatory activities of the Regional Board. The quantity of storm flow is obviously highly variable; programs to control its quality are in their nascent stages. For these reasons, water quality objectives for controllable constituents are set based on the base flow of the river, rather than on total flow.

The regulatory activities of the Regional Board include setting waste discharge requirements on point source discharges. Waste discharge requirements are developed on the basis of the limited assimilative capacity of the river (see TDS and Nitrogen Wasteload Allocation, Chapter 5). Nonpoint source discharges, generally urban runoff (nuisance water) and agricultural tailwater, will be regulated by requiring compliance with Best Management Practices (BMPs), where appropriate. The rising water component of base flow will be affected by the extraction of brackish groundwater in several subbasins (a Basin Plan implementation action), by regulation of wastewater discharges, and other activities.

In order to determine whether the water quality and quantity objectives for base flow in Reach 3 are being met, the Regional Board will collect a series of grab and composite samples when the influence of storm flows and nontributary flows is at a minimum. This typically occurs during August and September. At this time of year, there is usually no water impounded behind Prado Dam. The volumes of storm flows, rising water and nonpoint source discharges tend to be low. The major component of base flow at this time is municipal wastewater. The results of this sampling will be compared with the continuous monitoring data collected by USGS and data from other sources. These data will be used to evaluate the efficacy of the Regional Board's regulatory approach, including the TDS and nitrogen wasteload allocations (see Chapter 5). Additional sampling in Reach 3 by the Board and other agencies will help evaluate the fate and effects of the various constituents

of base flow, including the validity of the 50% nitrogen loss coefficient (discussed in Chapter 5).

Future river flows and quality (TDS and TIN) were projected by computer models. The results indicate that the objectives for TDS and total nitrogen will be met. The objectives for individual mineral constituents are expected to be met if the TDS objective is met.

Prado Basin Surface Water Management Zone

As discussed in Chapter 3 – Beneficial Uses, the Prado Basin Management Zone (PBMZ) is generally defined as a surface water feature within the Prado Basin. It is defined by the 566-foot elevation above mean sea level along the Santa Ana River and the four tributaries to the Santa Ana River in the Prado Basin (Chino Creek, Temescal Creek, Mill Creek and Cucamonga Creek). Nitrogen, TDS and other water quality objectives that have been established for these surface waters that flow within the proposed PBMZ are shown in Table 4-1. For the purpose of regulating discharges that would affect the PBMZ and downstream waters, these surface water objectives apply. This application of the existing surface water objectives assures continued water quality and beneficial use protection for waters within and downstream of the PBMZ.

“MAXIMUM BENEFIT” WATER QUALITY OBJECTIVES

As part of the 2004 update of the TDS/Nitrogen Management plan in the Basin Plan, several agencies proposed that alternative, less stringent TDS and/or nitrate-nitrogen water quality objectives be adopted for specific groundwater management zones and surface waters. These proposals were based on additional consideration of the factors specified in Water Code Section 13241 and the requirements of the State's antidegradation policy (State Board Resolution No. 68-16). Since the less stringent objectives would allow a lowering of water quality, the agencies were required to demonstrate that their proposed objectives would protect beneficial uses, and that water quality consistent with maximum benefit to the people of the state would be maintained (thus, the use of the term “maximum benefit” water quality objectives).

Appropriate beneficial use protection/maximum benefit demonstrations were made by the Chino Basin Watermaster/Inland Empire Utilities Agency, the Yucaipa Valley Water District and the City of Beaumont/San Timoteo Watershed Management Authority to justify alternative “maximum benefit” objectives for the Chino North, Cucamonga, Yucaipa, Beaumont and San Timoteo groundwater management zones. These “maximum benefit” proposals, which are described in detail in Chapter 5 – Implementation, entail commitments by the agencies to implement specific projects and programs. While these agencies' efforts to develop these proposals indicate their strong interest to proceed with these commitments, unforeseen circumstances may impede or preclude it. To address this possibility,

this Plan includes both the "antidegradation" and "maximum benefit" objectives for the subject waters (See Table 4-1). Chapter 5 specifies the requirements for implementation of these objectives. Provided that these agencies' commitments are met, then the agencies have demonstrated maximum benefit, and the "maximum benefit" objectives included in Table 4-1 for these waters apply for regulatory purposes. However, if the Regional Board finds that these commitments are not being met and that "maximum benefit" is thus not demonstrated, then the "antidegradation" objectives for these waters will apply. Chapter 5 also describes the mitigation requirements that will apply should discharges based on "maximum benefit" objectives occur unsupported by the demonstration of "maximum benefit".

COMPLIANCE WITH OBJECTIVES (Amended by Resolution No. 00-27, May 19, 2000)

"The Regional Board recognizes that immediate compliance with new, revised or newly interpreted water quality objectives adopted by the Regional Board or the State Water Resources Control Board, or with new, revised or newly interpreted water quality criteria promulgated by the U.S. Environmental Protection Agency, may not be feasible in all circumstances. Where the Regional Board determines that it is infeasible for a discharger to comply immediately with effluent limitations specified to implement such objectives or criteria, compliance shall be achieved in the shortest practicable period of time, not to exceed ten years after the adoption or interpretation of applicable objectives or criteria. This provision authorizes schedules of compliance for objectives and criteria that are adopted or revised or newly interpreted after the effective date of this amendment July 15, 2002.

NOTE:

- The names and areas shown on this map are the same as used by the Department of Water Resources (DWR) in their Bulletin 130 Series except as explained below.
- The numbering system used on this map is an adaptation of the numbering system used in the 130 Series.
- The boundary between Region 6 and Region 4 follows the boundary between Santa Ana County and Orange or San Bernardino Counties, not the Hydrologic Boundary. The San Bernardino County line splits Hydrologic Unit 1 (Santa Ana River HU) so that Sub-Areas 481.21, 481.22, and 481.23 are in Region 4 but drain into Region 6. The Orange-San Gabriel River HU is split into Sub-Areas 845.15, 845.81, 845.62 and 845.63 are locally in Region 6 but drain into Region 4. Therefore, a 5 digit number on the map indicates that a regional boundary crosses a hydrologic unit, area or subarea. In these cases, the hydrologic area number of the region from which the hydrologic area number of the region is separated by the regional boundary. All other digits are as described in the legend.
- The 1986 updated names shown on the map are in accordance with agreement with DWR and US Geological Survey.

1. INTRODUCTION

A. Clean Water Act

The federal Clean Water Act (CWA) established a national policy designed to help maintain and restore the physical, chemical and biological integrity of the nation's waters. In 1972, the CWA established the NPDES permit program to regulate the discharge of pollutants from "point sources" to waters of the United States. From 1972 to 1987, the main focus of the NPDES program was to regulate conventional point pollutant sources such as sewage treatment plants and industrial facilities. As a result, on a nationwide basis, "non-point sources", including agricultural runoff and Urban Runoff, now contribute a larger portion of many kinds of Pollutants than the more thoroughly regulated sewage treatment plants and industrial facilities.

B. MS4 Program Goal

The goal of the Municipal Separate Storm Sewer System (MS4) program is to manage the quality of Urban Runoff to prevent impacts to Receiving Waters. To this end, the Permittees developed a Consolidated Program for Water Quality Monitoring (CMP) that included monitoring at selected stations throughout the Permittees' collective jurisdictional boundaries. The original CMP was drafted in March 1994 and was included with the application materials for the previous round of permits. The CMP was accepted by the Colorado, San Diego and Santa Ana RWQCBs in 1995 as part of their respective permit applications. Subsequently, the RWQCBs directed the Riverside County Permittees to implement the CMP in the "second round" MS4 permits. In addition, in reissuing the MS4 permit for the Santa Margarita Region, USEPA Region IX directed the implementation of the CMP. The CMP is being updated to more effectively address the monitoring program objectives and the requirements of the third round MS4 permits issued by the Colorado and Santa Ana RWQCBs in 2001 and 2002, respectively. Additional revisions are anticipated to address the requirements of the MS4 permit for the Santa Margarita Region that is scheduled to be reissued in April 2004.

C. MS4 Functions

The primary purpose of MS4s is to protect life and property from the impacts of unconfined flooding. Flood prevention protects the environment by protecting materials from exposure to flood waters. For example, flooding of homes or commercial or industrial facilities would result in inundation of stored materials and liquid and solid wastes. This would result in the release of Pollutants to Receiving Waters, even if those materials and wastes were properly stored and managed using appropriate BMPs. In addition, unconfined flooding often results in the discharge of sanitary wastes to Receiving Waters. MS4s protect receiving waters from environmental damage that may result from such releases. An additional objective of the regional MS4 in Riverside County is water conservation. The District also allows public agencies to use the MS4 for water transfers to facilitate water conservation. Even though most of the point sources have brought the quality of their discharges under control or sent their wastes to a treatment facility, there are existing water quality impairments in Riverside County.

Many non-point sources, including agricultural discharges and discharges from open space and government lands not under the jurisdiction of the Permittees, are not treated or are inadequately treated and may be discharged into an MS4 or Receiving Water. In most cases, discharges to MS4s receive no additional treatment. It is important that the nature of all sources of Pollutants contributing to these impairments, including Urban Runoff, be characterized, both in identifying the types and amounts of Pollutants present, and in identifying the point and non-point sources most likely to have contributed to the Pollution. For purposes of the MS4 permits, the nature of discharges from urban land uses need to be characterized and controlled.

D. Climate and Flow Conditions

Precipitation patterns in Southern California are complex compared with the eastern and central United States. In Riverside County alone, there is a coastal influence, one east-west and two north-south trending mountain ranges with intermediate valleys, and a major desert. In a matter of minutes one can travel from an area where convective storms are the most critical to one influenced primarily by orographic conditions. Average annual precipitation is generally correlated with altitude. The climate in the Santa Margarita and Santa Ana Regions is characterized as semi-arid with an average annual precipitation of 11-14 inches in the urbanized areas of the Santa Ana Region and 12-16 inches in the urbanized areas of the Santa Margarita Region. The climate in the Whitewater Region is characterized as arid, with an average annual precipitation of 4-6 inches in the urbanized areas. Due to the climate, geology, geography, and development conditions, the flows in the MS4s are generally ephemeral or intermittent.

E. Potential Pollution Sources

Even though most point sources have brought the quality of their discharges under control or sent their wastes to a treatment facility, there remain water quality impairments in Riverside County. These impairments are nutrients and suspended solids in the San Jacinto watershed, elevated bacterial levels in the Santa Ana River and phosphorous in Murrieta Creek. Urban Runoff is believed to contribute to each of these impairments. Many non-point sources, including agricultural discharges and discharges from open space and government lands not under the jurisdiction of the Permittees, are not treated or are inadequately treated and may be discharged into an MS4 or Receiving Water. In most cases, discharges to MS4s receive no additional treatment. It is important that the nature of all sources of Pollutants contributing to these impairments, including Urban Runoff, be characterized, both in identifying the types and amounts of Pollutants present, and in identifying the point and non-point sources most likely to have contributed to the Pollution. For purposes of the MS4 permits, the nature of discharges from urban land uses need to be characterized and controlled.

Sources of Pollutants in Riverside County include aerial deposition, motor vehicles, agricultural runoff and overflows from holding ponds, illegal dumping and discharges, overflows from fire suppression activities, and malfunctioning and leaking sanitary sewer systems or improperly treated discharges from publicly-owned treatment works (POTWs). Other sources may include improperly stored materials at industrial and commercial facilities, runoff from landscape irrigation and discharge of pool water from residences and apartments, and parking lot wash water. Although industrial and commercial facilities are required to have Waste Discharge Requirements or NPDES Permits, discharges may occur, whether by an accidental spill or a deliberate violation of an existing Permit. These point and non-point sources discharge to the MS4, where they may ultimately be conveyed to a Receiving Water. In arid and semi-arid Riverside County, dry-weather flows that reach the MS4 generally soak into the ground or evaporate long before reaching a Receiving Water. Even during smaller storms, the only rainfall that reaches an MS4 is what directly falls into one. In general, flow is only observed as a result of larger storms. Exceptions include flows from springs, rising groundwater, POTW discharges and water delivery discharges.

F. Coverage Under Three MS4 Permits

Riverside County is under the purview of three California Regional Water Quality Control Boards: the Colorado River (Whitewater) Region, the Santa Ana River Region, and the San Diego (Santa Margarita) River Region. The MS4 permit for the Whitewater Region was adopted in September 2001 and for the Santa Ana Region in October 2002. The current MS4 permit for the Santa Margarita Region was issued by USEPA Region IX in 1998. This permit is currently being drafted for reissuance with a target date of April 2004. Monitoring requirements are still in the discussion

stage with San Diego Regional Board staff. The CMP is intended to comply with the core programmatic elements of each of the watershed MS4 permits.

The Riverside County Flood Control and Water Conservation District (District) serves as the Principal Permittee in all three MS4 Permits. The 26 Co-Permittees are identified in the Glossary. As Principal Permittee, the District leads in the development of permit compliance programs, coordinates and prepares annual reports, and administers regional programs including public education, monitoring, and other requirements proscribed by Implementation Agreements with each watershed's Co-Permittees. Generally, as the MS4 Principal Permittee, the District processes contracts and service agreements for laboratory, consulting, and interagency services. Under the previous round of permits, the District has also been responsible for collecting samples required under the MS4 permits, ensuring that the samples are analyzed at a certified laboratory, and analyzing the resulting data. Co-Permittees may also conduct monitoring activities, such as water quality sampling and field reconnaissance, either under the umbrella of the CMP or due to MS4 permit-specific monitoring requirements.

G. CMP Elements

The five program elements of the CMP are:

- Field Reconnaissance
- Water Chemistry
- Toxicity
- Bioassessment
- Special Studies

These elements will be described in more detail later in this document.

H. Revisions to CMP

This document represents a major revision to the original CMP and will be revised as new developments are made to program elements and as MS4 permit requirements change. As already noted, MS4 permits have been recently renewed for the Santa Ana and Whitewater Regions, and the CMP recognized their monitoring programs. The MS4 permit for the Santa Margarita Region is scheduled for adoption in April 2004, and the CMP will be re-evaluated to incorporate its monitoring program.

2. GOALS AND OBJECTIVES

As previously stated, the goal of the MS4 Urban Runoff program is to manage the quality of Urban Runoff to prevent impacts to Receiving Waters within the Permittee's collective jurisdictions. The objectives necessary to support this goal are as follows:

- Develop and support an effective MS4 management program.
- Identify those Receiving Waters, which, without additional action to control Pollution from Urban Runoff, cannot reasonably be expected to achieve or maintain applicable Water Quality Standards.
- Characterize Pollutants associated with Urban Runoff and assess the influence of Urban land uses on Receiving Water quality.

- Analyze and interpret the collected data to identify trends, if any, both to prevent impairments through the implementation of preventive BMPs and to track improvements based on the MS4 management program.

3. EPA GUIDANCE

The information in this section is largely taken from EPA's NPDES Storm Water Sampling Guidance Document (EPA 833-B-92-001), which provides recommendations on the frequency and method of collecting samples.

A. Nature of MS4 Discharges

Urban Runoff is a complex blend of countless diverse point and non-point sources conveyed in such a way that they outlet at measurable points. The non-point inputs are varied, and, in Riverside County, include significant inputs from open space, agricultural, and other non-Urban sources. The Permittees also lack legal jurisdiction over storm water discharges into their respective MS4s from agricultural activities, California and federal facilities, utilities and special districts, Native American tribal lands, wastewater management agencies and other point and non-point source discharges otherwise permitted by or under the jurisdiction of the Regional Board. Further, certain activities that generate pollutants present in Urban Runoff, including operation of internal combustion engines, atmospheric deposition, brake pad wear, tire wear, residues from lawful application of pesticides, nutrient runoff from agricultural activities, and leaching of naturally occurring minerals from local geography, are beyond the ability of the Permittees to eliminate. The USEPA has recognized this situation by holding Urban Runoff standards to "Maximum Extent Practicable" as opposed to the "Best Available Technology" standard for Industrial waste streams.

Industrial waste streams are relatively constant and consistent in chemical composition and flow; there are no engineering controls on Urban Runoff other than gross flow control and Best Management Practices. The chemical makeup of the MS4 discharges may also differ immensely by location, from storm to storm and even during a storm. The volumetric rate of Urban Runoff in Riverside County may vary from nonexistent to hundreds of cfs. During dry weather, inputs to the MS4 may include industrial accidents, broken sprinkler or pressure mains, rising ground water, sanitary sewer overflows, agricultural irrigation discharges, and intentional discharges. Flows may enter the MS4 from sheet flow, through a pipe, or through an illicit connection cut into the wall of a MS4. Deciding where to sample the MS4 is problematic because of the vast number of discharge locations to the MS4 and discharge locations from the MS4 to Receiving Waters. The manpower and expense that would be necessary to monitor every possible entrance and discharge location would outstrip available resources for implementation, and would overload the capacity of many contract analytical laboratories. The CMP proposes a sampling plan that includes representative land use and Receiving Water stations to generally characterize land uses and Receiving Waters, provides for the removal of illicit discharges, and makes the best use of available resources.

B. Representative Storm

The USEPA guidance document states that three different storm events should be sampled each year. A "representative" storm is defined as:

- Greater than 0.1 inch accumulation;
- Preceded by at least 72 hours of dry weather; and
- Where feasible, the depth of rain and duration of the event should not vary by more than 50 percent from the average depth and duration.

These criteria were established to:

- Ensure adequate flow;
- Allow Pollutants to build up during the dry weather intervals; and
- Ensure that the storm would be typical for the area in terms of intensity, depth, and duration.

In ephemeral watersheds, the USEPA's recommended storm may not generate sufficient flow in the MS4 to sample. For example, in a dry watershed, rainfall will soak into the ground and will not generate runoff. A subsequent storm on a saturated watershed may generate substantial flow in portions of the MS4. Therefore, a storm is further defined as

- one in which there is sufficient flow to collect a sample.

The District has prepared guidance on when wet-weather sampling should be initiated (See Section 4.B).

USEPA's wet weather sampling guidance recognizes that it may not be feasible to collect a sample. For instance, flow in a channel may be too swift for safe collection or lightning may be active in the area. Also, antecedent conditions may preclude generation of adequate runoff, and there may not be sufficient flow to allow collection of a sample adequate for analysis. In cases such as these, attempts to collect a sample should be noted and submitted to the Regional Board for their certification.

C. Composite Sampling

Composite sampling is required for most MS4 permits. Composite samples are intended to characterize the average quality of the entire storm water discharge. The most accurate type of composite sampling is flow-weighted, where the amount of sample collected is proportional to the flow rate. Composite samples may be collected manually (as outlined in the CMP) or with the use of an automatic device. However, there are several problems inherent in using an automatic sampler. As several pollutants must be measured in the field, including pH and temperature, no reduction in field staff requirements will be realized with the use of automatic samplers. Other concerns include that biological indicators of sanitary contamination, such as fecal streptococcus, fecal coliform and chlorine have very short (i.e., 6 hours) holding times. Collection of samples for oil and grease requires teflon-coated equipment to prevent adherence to the sampling equipment. Volatile organic compounds (VOCs) are likely to volatilize as a result of agitation during automatic sampler collection and/or may contaminate other samples already collected. Also, pH, temperature, cyanide, total phenols, residual chlorine, oil and grease, fecal coliform, and fecal streptococcus tend to transform to different substances or change in concentration after a short period of time, particularly in the presence of other reactive pollutants. The requirements for grab sampling are stated in 40 CFR 122.21(g)(7). Outside of water quality issues, equipment vandalism is a common occurrence. Replacing the equipment is expensive and it takes time for replacement equipment to be delivered.

Sampling across the hydrograph, using flow-weighted proportions, results in the most accurate estimate of mass loading of a Pollutant for a given storm. However, knowing when and for how long to sample is problematic as it is not possible to predict storm duration or intensity, and the resulting flow conditions, to the accuracy needed to calculate mass loading. Storms in Southern California are often of short duration and high intensity. The "storm" may actually consist of many spotty periods of rainfall with a half-hour or so between cloudbursts. In addition, precipitation is generally inconsistent across a watershed as "storms" generally move across a watershed in cells. Hydrographs in Riverside County are very spiky and the rise and fall cannot be determined until

after the storm has passed. USEPA's guidance document states that the flow-weighted composite sample must be taken for either the first 3 hours of a storm or for the entire discharge (if the event is less than 3 hours long). For stop/start rains (rainfall is intermittent), the reference recommends that samples be taken until an adequate sample volume is obtained. In either event, the grab samples collected during the first 30 minutes of a storm event will generally contain higher concentrations of pollutants, since they pick-up pollutants that have accumulated since the last storm event and are on the rising arm of the hydrograph, i.e., there is less runoff for dilution. This guidance is implemented in the CMP.

A composite sample may be collected on a flow-weighted basis to estimate the load over a storm. The composited concentration is assumed to be the same over the course of the storm. Samples may be collected on an equal-time basis as long as flow is also measured or estimated at the time the sample is collected. The composite is proportioned according to the flow represented by the individual samples.

D. Sampling Locations

USEPA's guidance says that the ideal sampling location would be at the lowest point in the drainage area where a conveyance discharges storm water to Waters of the U.S. or to a MS4. Typical sampling locations may include the discharge at the end of a pipe, a ditch, or a channel. The sample point should be in a safe area that is easily accessible on foot.

In addition to considering USEPA guidance, the Permittees considered urban land uses in siting the sampling locations, although isolating an individual land use was not always possible. Reference stations have also been established in locations above the influence of Urban Runoff.

E. Challenges of Ephemeral Watersheds

During dry weather in an ephemeral MS4 where flows are not present except during storms, a better use will be made of finite resources to focus on reconnaissance of the MS4. This consists of visual inspection of the channels and determining the sources of flows found in the MS4. The flow may be coming from discharges permitted, allowed (e.g., springs), or exempted by a Regional Board (e.g., agriculture, water transfer discharges), but it may also be coming from an illegal discharge or an illicit connection. Once the source of the discharge is determined, steps should be taken to minimize or eliminate the flow. If the source cannot be determined, a sample should be collected and analyzed for parameters based on the surrounding land use. Use of the MS4 for water conservation transfers (e.g., imported water deliveries) may confound finding illegal discharges. In this situation, other possible sources of the non-storm water discharge should be examined and ruled out.

F. Video Reconnaissance

Extensive videotape "reconnaissance surveys" of the Permittees' underground MS4s and visual inspections of open channel facilities were completed in September 1994. The surveys revealed that illicit connections are essentially non-existent, and connections tended to occur to open facilities. Regular surveys of underground facilities require entry into confined spaces, and as illicit connections are not expected, would be putting municipal personnel at unnecessary risk. Reconnaissance surveys will be limited to open facilities, and if flows originate in underground facilities, they will be discovered during the survey.

4. CONSOLIDATED MONITORING PROGRAM

A. Field Reconnaissance

In an ephemeral watershed, this is the most important element of the monitoring program. The MS4 permits require that the Permittees effectively prohibit the discharge of non-storm water into their respective MS4s and to Waters of the U.S. During dry weather, regular surveys of their MS4s need to be conducted by each Permittee. If water is observed, its source must be located. If the water is associated with a permitted discharge, the facility owner would have laboratory analyses as required by their discharge permit issued by a Regional Board. Other discharges may be allowed as discussed below or may be required to be stopped by the jurisdictional Permittee.

1) *Allowed or Permitted Discharges*

40 CFR 122.26(d)(2)(iv)(B)(1) includes a provision that certain categories of discharges need not be prohibited. These categories are:

- Water line flushing;
- Landscape irrigation;
- Diverted stream flows;
- Rising ground waters;
- Uncontaminated ground water infiltration [as defined at 40 CFR 35.2005(20)] to MS4s;
- Uncontaminated pumped ground water;
- Discharges from potable water sources
- Foundation drains;
- Air conditioning condensation;
- Irrigation water;
- Springs;
- Water from crawl space pumps;
- Footing drains;
- Lawn watering;
- Individual residential car washing;
- Flows from riparian habitats and wetlands;
- Dechlorinated swimming pool discharges;
- Street wash water; and
- Non-emergency fire fighting flows.

MS4 permits may include additional exempt discharge categories. Permits may also prohibit one or more of the aforementioned discharge categories if they have been shown to contribute pollutants within a particular watershed. Discharges covered by an NPDES permit, Waste Discharge Requirements, or waivers issued by the Regional or State Board are not prohibited from entering a MS4, but they also do not have to be accepted by the jurisdictional Permittee.

2) **When to Sample**

The following procedure is recommended in determining when to collect samples and what level of analysis is necessary. See the suggested equipment list under Section B, Water Chemistry for a suggested equipment list for field personnel.

- a) ~~No action is required where the source is determined to be a permitted, allowed, or exempted discharge.~~
- b) If a permitted, allowed, or exempted discharge is exposed to a source of pollutants (e.g., recently-applied fertilizers or pesticides) it will be treated as an illegal discharge.
- c) Where an illegal discharge is identified, actions will be implemented to eliminate the source of discharge until the discharger is able to obtain a permit from the jurisdictional Regional Board and the discharge is determined to be acceptable by the Permittees. In addition, at least one sample of the discharge will be collected and analyzed as specified in items e) and f) below for evidence in a complaint investigation.
- d) At each site inspected or sampled, record general information such as time since last rain, quantity of last rain, site description (e.g., conveyance type, dominant land uses), flow estimation (e.g., width of water surface, approximate water depth, approximate flow rate), and visual observations (e.g., odor, color, clarity, floatables, deposits/stains, vegetation condition, structural condition, and biology).
- e) Field screening will be conducted when the source of a discharge cannot be determined or as part of a complaint response. At a minimum, the following field screening analyses should be made:
 - Specific conductance and/or total dissolved solids
 - Turbidity
 - pH
 - Temperature
 - Dissolved Oxygen
- f) If field screening indicates potential water quality impairment (e.g., very high specific conductance, total dissolved solids, or turbidity, pH below 6 or above 9, dissolved oxygen below 4 mg/L), and/or visual observations in the area of the discharge indicate the presence of Pollutants (e.g., staining, water sheen, water color and/or odor, algae, foaming), a sample should be collected for laboratory analysis. The decision of what parameters to monitor should be based on the visual observations, the types of nearby businesses or land uses, and history of complaints in the area. Suggested parameters include:
 - Total Hardness
 - Oil and Grease
 - Cadmium (Dissolved)
 - Copper (Dissolved)
 - Lead (Dissolved)
 - Zinc (Dissolved)

- Diazinon and Chlorpyrifos (or another suspected pesticide, if use in the area is known)
- Enterococcus
- Total Coliform
- Fecal Coliform

g) Where visual investigations do not result in identification of the source of non-storm Urban Runoff, water quality samples will be collected and analyzed as specified in the previous bulleted item to assist in source identification and potential enforcement action.

Follow up activities should be undertaken to ensure that undesired flows have been ceased.

B. Water Chemistry

This section addresses monitoring requirements that are common to all three watershed MS4 permits. Permit requirements that deviate from this protocol will be outlined in the watershed-specific appendix.

1) Need for Both Chemistry and Flow Data

Chemical data allow for comparisons with Basin Plan Objectives and among monitoring stations. An understanding of impacts, however, requires an understanding of the flows throughout the MS4 and Receiving Waters. For example, a water quality analysis may indicate a high concentration of a pollutant in an MS4, but flows may be very low and visual observation may show that the flow will not reach a Receiving Water. Development of a watershed computer model may be an effective approach to understand the impacts of point and non-point discharges. However, establishing and maintaining a watershed computer model requires both chemical and flow data.

2) Wet-Weather Monitoring

The MS4 permits require that wet-weather samples are to be collected from the first storm event that produces flow and two more storm events during the rainy season. The definition of wet season may differ by watershed, but in general falls between October 1 and April 30. In an ephemeral watershed, the first storm of the year that falls under the USEPA-recommended criteria may not result in runoff from surrounding properties. The District has developed guidance on when wet-weather samples should be collected. Two National Weather Service weather forecasts are monitored, the normal 7-day forecast for the possibility of a rain event and the Qualitative Precipitation Forecast (QPF) to determine how much rain is predicted to fall in 6-hour increments over the next 24-hour period and during days 2 and 3 of the rain event. The antecedent moisture condition (AMC) of the watershed is also evaluated. AMC is a subjective measure of runoff potential. AMC I represents low runoff potential, such as from a dry watershed. AMC II represents moderate runoff potential. AMC III represents high runoff potential, such as a watershed saturated from previous rain events. Based on the QPF and AMC, the following guidelines are recommended in determining when a wet-weather sample should be collected:

- AMC I and QPF of $\frac{1}{2}$ inch of precipitation in 24 hours
- AMC II and QPF of $\frac{3}{8}$ inch of precipitation in 24 hours
- AMC III and QPF of $\frac{1}{4}$ inch of precipitation in 24 hours

These guidelines may be modified based on differences in hydrology in a particular drainage area.

During the first storm event, the analysis may include the entire priority pollutant list (Table 1). Other analyses may include a subset of the priority pollutant list or may include parameters listed in Table 2. If Constituents of Concern (e.g., parameters that exceed an applicable Basin Plan Objective) that could impact aquatic habitat (e.g., metals) are identified, sediment samples may be collected and analyzed for those parameters.

3) *Dry-Weather Monitoring*

A minimum of two dry-weather samples should also be collected to determine the effects of seasonality, if they exist. In an ephemeral watershed, monitoring efforts will be focused on characterizing flows that cannot be traced to a source during field reconnaissance.

4) *Factors Influencing the Nature of Urban Runoff*

Regular monitoring is needed to assess the quality of Urban Runoff, identify seasonal differences, and determine if Urban Runoff is impacting Receiving Waters. Several factors influence the nature of Urban Runoff:

- Land Use – Certain types of Pollutants may be expected from specific land use categories. For example, metals and organics may be found in industrial wastes, nutrients may be found in agricultural return flows and precipitation, and pesticides and herbicides may be found in residential or commercial landscaped areas.
- Season – As Riverside County is arid or semi-arid, most of the Receiving Waters are ephemeral or at most intermittent. During dry weather the only flows that discharge to Receiving Waters are rising groundwater, water conservation transfers, treated sanitary sewer effluent, discharges from sources not under control of the Permittees, and illegal discharges. During dry weather Urban Runoff flows carried by MS4s tend to evaporate or soak into the ground before they reach a Receiving Water. During small storms, the only stormwater entering a MS4 is what directly falls on it as precipitation or from highly paved adjacent surfaces. Only during larger storms will the watershed become sufficiently saturated for surface runoff to be generated and sustain continued flows in a MS4.
- MS4 Type – Discharges entering an earthen channel will absorb into the stream bed and will sustain flows only when the stream bed is saturated. Low-volume discharges to concrete-lined channels may evaporate before reaching a Receiving Water. During large storms, both types may sustain flows for several days following the storm.
- Storm Interval – A watershed may still be saturated for several days after a significant rainfall event. A subsequent storm may sustain flows through an MS4 and carry additional Pollutants. After a few weeks, the watershed may have dried enough that flows will not occur.
- Illicit and Accidental Discharges – Pollutants may be intentionally discharged directly or indirectly into a MS4. Examples range from the illegal discharge of wastewater from mobile operations into a MS4 to legal discharges of overflow water to a MS4 from fire-suppression activities.

5) *Sampling Procedure and Recommended Equipment*

For safety reasons and to minimize sample contamination, at least two people are recommended for each sampling team. Samples need to be collected in a way that minimizes disturbance of sediments and avoids introduction of additional contaminants. The USGS

recommends a "Clean Hands/Dirty Hands" technique, in which the "Clean Hands" (CH) person conducts the tasks related to direct contact with the sample bottles and record-keeping and the "Dirty Hands" (DH) person collects the samples and makes equipment and gauge readings.

When collecting samples, CH fills out the labels, places them on the bottles, opens the bottles, and hands the bottles to DH. DH takes the bottles and either fills them directly from the flow or uses a pole sampler or bucket to collect the water and pours the water into the bottle. DH also fills a bucket or cup with water for the field meters and reads the measurements to CH. After samples are collected, the field data sheet needs to be filled out and the bottles placed in the ice chest. The chain of custody form can be filled out as the samples are collected or prior to arrival at the lab, where the information is transcribed from the field data sheet. Sampling equipment should be as inert as possible (e.g., glass, stainless steel, teflon) to minimize the introduction of contaminants that could leach from the sampling equipment. Sampling equipment, such as a bucket, that is reused during a sampling event should be thoroughly wiped clean with a fresh towel or wipe after a sample is collected and rinsed at least three times in the water to be sampled before the next sample is collected.

Sampling equipment should be stored in a secure location where it can be accessed when needed. There should be a working power source for charging batteries. A work table is needed to hold materials to calibrate field equipment and make repairs. A sink is needed for cleaning equipment and rinsing non-hazardous calibration standards. Hazardous materials should be properly stored and disposed of.

Flow measurements may be:

- Determined by using an available USGS flow gauge. During storm sampling, uncalibrated flows will be used in determining proportions for preparing a flow-weighted composite.
- Calculated where there is a staff gauge and knowledge of channel geometry. A calibration curve will be available that correlates gauge height and volumetric flow.
- Estimated by dropping a floatable object such as a leaf or twig in the water, timing how long it takes to move from one landmark to another, measuring the distance between the two landmarks. With knowledge or an estimate of the channel cross-sectional area, the volumetric flow rate may be calculated as $\text{area} * \text{distance}/\text{time}$.
- Where flows are very low or not amenable to the measurement methods noted above, a visual estimate will be recorded based on the experience of the field staff.

Suggested equipment list:

- Note pad
- Pen or pencil
- Ice chest
- Ice
- Sampling Bottles
- Chain of Custody forms from the contract laboratory
- Field Data Sheets
- Labels for sampling bottles
- Powder-free gloves, such as nitrile or latex
- Leather or heavy cloth gloves
- Orange or yellow rain gear or safety vest
- Multimeter or individual meters that measure temperature, pH, TDS, conductivity, turbidity, dissolved oxygen
- Bottle carrier
- Pole sampler
- Rope
- Lanyard
- Bucket(s)
- Facility map(s) or map book
- General map book
- Cell phone
- Camera (digital or film)
- Steel tape (to measure flow depth if no flow or staff gauge)
- PVC boots and/or hip waders
- Trash bags
- Hand sanitizer
- Towels and/or rags
- First aid kit
- Fire extinguisher
- Flashlight and/or spotlight
- Jumper cables
- List of office phone numbers and/or other team cell phone numbers
- Vehicle with full gas tank
- Keys to open access locks
- Extra locks (in case replacements are needed)
- Short length of chain
- Bolt cutters
- Tool Box

The contract laboratory should provide the necessary bottles. Some tests require the use of preservatives, usually an acid, in the sample bottle. The contract laboratory provides the preservative in the bottle.

6) Safety

Safety of the sampling team is paramount. The field vehicle should start out with a full tank of gas and be in good repair. Extra care must be taken when driving at night or in the rain. If the sampling location is unsafe, make note of the unsafe situation and do not collect a sample or come back after the hazardous situation has ceased.

7) Irreducible Concentrations

One of the purposes for collecting water quality data is to evaluate BMP performance. For example, studies have been conducted that evaluate percent reductions of various Pollutants. In addition, GeoSyntec Consultants, in cooperation with the Urban Water Resources Research Council of the American Society of Civil Engineers and USEPA's office of Water, prepared a guidance manual that provides an overview of BMP monitoring, discusses difficulties in assessing BMP performance, and addresses "the relationship between BMP study design and the attainment of monitoring program goals." The manual presents a table (Table 2.9, page 33) of "irreducible concentrations," the lowest concentration that can possibly be achieved using existing BMPs, of selected Pollutants. The table, reprinted below, is:

Contaminant	Irreducible Concentration
Total Suspended Solids	20 – 40 mg/L
Total Phosphorus	0.15 – 0.2 mg/L
Total Nitrogen	1.9 mg/L
Nitrate as Nitrogen	0.7 mg/L
Total Kjeldahl Nitrogen	1.2 mg/L

C. Toxicity

Toxicity testing may provide for the assessment of impacts a discharge may have on aquatic life. Studies throughout California have shown that the most common sources of toxicity are pesticides, such as diazinon and chlorpyrifos, and metals.

1) Typical Method

The toxicity tests were developed using East Coast species in perennial flow conditions. Difficulties have been encountered in the use of toxicity tests for POTWs in ephemeral systems as no dilution occurs in the Receiving Water and the species the tests are based on may do poorly if at all in ephemeral flow conditions, even in the absence of treated effluent or Urban Runoff discharges. Additionally, if marine species are used, changing the water chemistry (e.g., salinity, pH, temperature) to ensure survival of the test species may create conditions, unrelated to the original test water, which could be toxic to the test species. This could result in a false positive, and could lead to time-consuming and costly search for a toxicant that is an artifact of the test procedure.

Many times, the drainage area contributing flows to a station selected for toxicity testing will include land uses other than Urban, such as agriculture, parks, and state and federal lands. Repeated indications of toxicity, even after the implementation of measures to control the toxicant(s)' presence in Urban Runoff, may indicate that the toxicants are being contributed from these other land uses, which are outside of the Permittee's ability to control. Therefore, the presence of toxicity does not in itself indicate that Urban Runoff is contributing to Receiving Water impairment.

The MS4 permits generally specify the species to be tested and under what conditions the samples are to be collected. If toxicity is found, the source must be determined and reduced or eliminated. The procedure to find the source is a Toxicity Identification Evaluation (TIE) and to reduce it is a Toxicity Reduction Evaluation (TRE). The MS4 permits usually require that a criteria be identified that will trigger the initiation of TIEs and TREs. The County of San Diego utilizes a "triad approach" decision matrix that includes actions to be undertaken based on the results of chemical, toxicity, and bioassessment tests at a single station. This decision matrix is being reviewed by the Southern California Stormwater Monitoring Coalition for applicability to ephemeral watersheds.

2) Alternate Method

Toxicity tests and TIEs are expensive (see Table 3). Toxicity tests conducted on MS4s throughout the state have determined that the most common sources of toxicity in Urban Runoff are diazinon, chlorpyrifos, and metals. Having to repeatedly confirm the presence of these toxicants will divert resources that could better be used in Pollutant source reduction and BMP implementation.

In light of this, an alternate approach is to conduct a TIE at a station at the bottom of the watershed. Since this station will include land uses other than urban, the tests run should focus on pesticides, metals, and other common sources of toxicity typically associated with Urban Runoff. If toxicity is found, and the toxicants can be associated with Urban Runoff, the inspection, IC/ID, and education programs may need to be expanded to address the identified Urban Runoff sources of toxicity. Positive indications of toxicity should be confirmed before additional activities are implemented. Further TIEs would not need to be conducted as the identified source(s) of toxicity would be assumed to be present, unless proved otherwise, during the remaining term of the MS4 permit. Chemical monitoring could be used to determine if chemical concentrations of identified toxicants are decreasing.

In the fifth year of the MS4 permit term, prior to permit renewal, a TIE would be conducted and confirmed to determine if these sources of toxicity are still indicated. Repeated presence of toxicity using this alternate method may indicate that sources other than Urban Runoff, such as agriculture or activities on state or federal lands, are contributing Pollutants, and that other regulatory approaches by the Regional Boards are necessary to address those sources.

Table 3 includes a list of toxicity tests required or recommended in the MS4 permits, the volume of water required, and the cost. MS4 permit-specific requirements are outlined in the watershed-specific appendix. Toxicity testing requires personnel with proper equipment and expertise in handling the test species, and therefore should be conducted by a contract laboratory.

D. Bioassessment

Bioassessment may be used to assess the cumulative impacts of discharges to water-supported native stream species including benthic invertebrates, algae, fish and plants. It is the direct measurement of the biological and physical condition of a watershed. Additionally, bioassessment may provide a direct measurement of the impacts of cumulative, sub-lethal doses of pollutants that may be not be detectable in a water chemistry analysis, but that may still have biological effects, therefore, it may detect impacts that chemical and toxicity monitoring cannot. However, there are some limitations to this method. From USEPA's Rapid Bioassessment Protocol guidance, an accurate assessment of stream biological data is difficult because natural variability cannot be controlled. Unlike analytical assessments conducted in the laboratory, in which accuracy can be verified in a number of ways, the accuracy of field assessments cannot be objectively verified. For example, it isn't possible to "spike" a stream with a known species assemblage and then determine

the accuracy of a bioassessment method. Depending on which methods are chosen, the actual structure and condition of the assemblage present or the trends in status of the assemblage over time may be misinterpreted.

USEPA protocol allows the use of fish, macroinvertebrates, periphyton (algae), and macrophytes (plants). The MS4 permits currently require the use of the macroinvertebrate protocol. Extreme care must be taken when conducting bioassessments. Bioassessment includes comparing the biological integrity of the monitoring station with that of a reference station. Differences in habitat quality between a reference and the monitored station could lead to false indications of impairment. For example, if a bioassessment indicator species is found at the reference station but not at a monitored station or at a reduced population, it may indicate the presence of toxicity, or it may be due to the lack of specific habitat necessary for their survival at the monitored station. For this reason, it is important that the reference station represent the same hydrogeology as the monitoring stations.

Bioassessment requires personnel with expertise in identifying and classifying the target species, and therefore is better done by a contract laboratory.

E. Special Studies

Special studies may be needed to address unique watershed-based issues or to answer specific questions that the routine monitoring program may generate. Generally, special studies are short-term efforts with a predefined goal. As research, special studies are often expensive, and may be beyond the expertise and/or ability of the Permittees to fund without outside state and federal sources. Special studies do not have to involve field investigation. Where watershed issues are not unique, special studies may consist of a literature review and a discussion of the applicability of the findings to the identified issue.

5. MONITORING COSTS

Monitoring costs include monitoring program design, establishment of monitoring stations, equipment purchase and installation, field time, sampling time, laboratory analysis, flow gauge operation and maintenance, data management and analysis, reporting, regulatory coordination, contract administration, training, other staff time, and vehicle operation. Costs can vary greatly; for example, a TMDL station requires an installed flow gauge that can cost upwards of \$17,000 for yearly operation. Alternatively, a staff gauge on the wall of a concrete channel may cost only \$100. Sampling over the course of a storm could take 12 hours of staff overtime, while dry weather monitoring is usually conducted during regular working hours.

Analytical costs for chemical analyses are included in Tables 1 and 2, and for toxicity testing in Table 3. Where there is no cost or water volume entry in Table 1, that parameter is part of the full USEPA priority pollutant screening, which costs approximately \$1000 per test. Bioassessment costs, which include collection and evaluation of three replicate samples, are approximately \$2200 per station.

6. QUALITY ASSURANCE/QUALITY CONTROL

The measurement of chemical constituents in Urban Runoff at the trace level is often difficult due to inherent variability of environmental samples, field sampling techniques, and analytical techniques. In order to assess and maximize data quality, a Quality Assurance and Quality Control (QA/QC) Plan is implemented as an integral part of the monitoring program. The QA/QC program is designed to enable an

evaluation and validation of the analytical data for representativeness, accuracy, and precision. The following text includes separate descriptions for the field and laboratory portions of the QA/QC program.

A. Field QA/QC Procedures

Several additional samples will be collected and analyzed to help identify potential sources of error introduced during the storm water sampling process. Procedures are being developed that will incorporate the following QA/QC samples:

Grab Sample Equipment Blanks – Assesses whether contamination is being introduced during the sampling process.

Grab Sample Duplicate – Assesses sampling and analytical precision.

Flow-Weighted Duplicate – Assesses analytical precision.

B. Laboratory QA/QC Procedures

Edward S. Babcock & Sons, Inc., located in Riverside, has been contracted by the Permittees to perform or to have a Permittee-approved subcontract laboratory perform all chemical analyses. The laboratory maintains a Quality Assurance Manual that is available on request.

The suite of chemical analyses for all storm water samples is shown in Tables 1 and 2. In addition to performing the analyses, the laboratory will make every effort to meet holding times and target detection limits for each analyte. The following laboratory QA/QC procedures will be followed for both the flow-weighted sampling program and the manual grab sampling program:

Standards – Calibration standards with known concentrations will be prepared and used in the laboratory to obtain instrument calibration curves in accordance with the provisions of the various analysis method specifications.

Method Blanks – Analyte-free water will be processed through all sample preparation procedures and analyzed as a method blank. One such method blank will be analyzed per storm event. This will provide an indication as to whether contamination is occurring as a result of laboratory procedures.

Internal Spikes – Internal spikes (matrix spikes) will be prepared in the laboratory by adding a known amount of target and or surrogate analyte(s) into a field sample prior to laboratory preparation. The matrix spike will be at one to five times the analyte concentration, based on prior analysis for the analyte. If the matrix spike is outside of the desired “one to five” range, a second spike will be required. Each of the spiked samples will also be analyzed in duplicate for an assessment of the analytical method precision. One internal spike will be analyzed per storm event.

C. Data Reduction, Validation and Reporting

Results of precision and contamination checks (described above) will be reviewed by an in-house chemist after each storm event. In the event that data quality objectives are not met, data will be qualified as necessary in the final data report.

D. Biological Parameters

Bacteria – Accuracy for bacteria will be determined by analyzing a positive control sample twice annually. A positive control is similar to a standard, except that a specific discreet value is not assigned to the bacterial concentrations in the sample. This is due to the fact that bacteria are alive

and capable of mortality and reproduction. Instead of a specific value, an approximate target value of the bacterial concentration is assigned to the sample by the laboratory preparing the positive control sample.

Benthic Macroinvertebrates – Aquatic Bioassay & Consulting Laboratories in Ventura conducts bioassessment monitoring for the Riverside County Permittees and maintains a Quality Assurance Manual. For benthic macroinvertebrate analysis, accuracy will be determined by having 20% of the samples (annually) re-analyzed and validated to CSBP Level 3 (genus level) by a professional taxonomist.

7. DATA COLLECTION AND ANALYSIS

A. Database

The District maintains its rainfall and water quality data in a proprietary integrated data management system known as Hydstra^{®1}. The Hydstra[®] software system was installed early in FY 1999-2000. It uses stringent quality control procedures and includes a set of data analysis and reporting procedures. Additional reports have been created under contract to improve presentation of the raw data. The District also uses Statistica[®] to develop reports and graphs that will later be implemented as part of Hydstra[®] or to prepare more complicated statistical analyses. Water quality data collected by other Co-Permittees may also be stored in the District's database.

B. Trend Analysis

Part of a proper statistical analysis is to plot the raw data (e.g., chemistry or mass load) and examine it to identify the existence of obvious patterns, such as seasonality, if they exist. Upward or downward trends should also be analyzed, if they exist. The data may be so scattered that no trend is apparent. Characteristics of Urban Runoff may vary significantly if collected during dry weather as opposed to during storm conditions.

In addition to evaluating trends in chemical concentrations over time, correlations and trends may also be determined between or among sets of parameters, for example, "Is there a correlation between changes in urban land use and metals concentrations?" Trends may also be evaluated spatially (cluster analysis), for example, "Do concentrations or mass loads tend to be higher in one geographical area?" As trends are identified, focused measures may be taken to reduce or eliminate sources of the identified Pollutant. Trend analysis may also allow proactive measures to be taken, for example, if concentrations of a particular Pollutant are rising.

The Permittees currently examine data for trends and make comparisons with Basin Plan Objectives (see Section C. below) in the Annual Report. The data are plotted as concentration vs. date both as the raw data and as box-and-whisker plots, which summarize statistical measures such as minimum, maximum, and average. Other analyses may be added, such as land use correlations or cluster analysis, to further utilize the water quality data in implementing the Permittees' Urban Runoff management program.

¹ Although Hydstra is a proprietary data management system, the program supports export of data in commonly used spreadsheet and database formats. The use of trademark or brand names does not connote a recommendation of a particular product.

C. Comparison with a Benchmark

If an appropriate benchmark exists, such as Basin Plan Objectives, direct comparisons may be made. It is possible that water quality data do not exhibit a clear trend, but still exceed a benchmark value.

Does exceedence of a benchmark in and of itself necessarily mean that the environment is being harmed or degraded? The classic SWRCB reference Water Quality Criteria (see Appendix F for citation) warned that water quality objectives were meant to represent "an aim or a goal toward which to strive, and it may represent an ideal condition that is difficult, if not impossible, of economic attainment. Most certainly, however, it does not imply strict adherence nor rigid enforcement by a regulatory agency." It also says that "[t]he fact that a standard has been established by authority makes it quite rigid, official, or quasi-legal. An authoritative origin does not necessarily mean that the standard is fair, equitable, or based on sound scientific knowledge, for it may have been established somewhat arbitrarily on the basis of inadequate technical data tempered by a cautious factor of safety. There is a tendency ... for regulatory authorities to promulgate standards of questionable scientific justification to serve as a crutch that facilitates administrative action and enforcement." This implies that based on numeric objective alone, exceedences may not indicate environmental harm. Toxicity testing and biological assessment may provide additional information needed to indicate whether environmental harm is occurring or has the potential to occur.

The Permittees have developed a report that lists the data collected on a given date. If a Basin Plan Objective exists and is exceeded, the report flags it. The District intends to print these reports as the monitoring results are submitted by the contract laboratory and forward them to the appropriate Permittee for follow-up, if necessary.

D. Calculating Mass Load

Mass load information is important in determining the amount of pollutant passing through a MS4, either instantaneously or over a period of time, such as during a storm event. Watershed models are based on mass load in addition to chemical concentrations and flow.

To calculate mass load over a storm, two approaches may be used.

- Assume that the concentration of a grab sample is constant over the storm event. Mass load is calculated as the concentration multiplied by the total flow over the storm period, or mass load = concentration * total flow. Adjustments for units may be necessary.
- Collect a flow-weighted composite of samples collected during a storm event and assume that the composite concentration (Event Mean Concentration, or EMC) is constant over the storm event. EMC is calculated as the sum of flow measured at the time a sample was collected multiplied by the concentration of that sample and the sum divided by the total flow over the storm period, or $EMC = \frac{\sum(\text{concentration} * \text{flow})}{\text{total flow}}$. Mass load is calculated as the EMC multiplied by the total flow over the storm period, or mass load = EMC * total flow. Adjustments for units may be necessary.

E. Consideration of Historical Data

Many sources of data exist. Historical water quality data may have been entered into USEPA's STORET (STORage and RETrieval) database. USGS also maintains a database of water quality and flow data they have collected. Other municipalities may have collected data that is stored in in-house databases or spreadsheets. These datasets may be useful in looking at long-term trends or in establishing baseline conditions.

Using historical data can be problematic. For example, detection levels for certain constituents may have been higher under older test methods. The level of quality control in collecting and analyzing the data may have been less rigorous, especially if an in-house, uncertified laboratory was used. The original paper records may have been lost, preventing the establishment of a paper trail to verify questionable data.

F. Power Analysis

A goal in developing a monitoring design is to detect trends in the data and take action based on those trends. For example, if water quality trends show that concentrations of a Pollutant are increasing and could exceed a benchmark value in the future, measures need to be taken to eliminate nonpermitted sources of that Pollutant. Trends may not be apparent in the short term due to natural variability, but may be more obvious over a longer period of time. Or more frequent monitoring may point out trends in a shorter period of time.

The statistical power of a monitoring design is its ability to detect a change, such as a trend, if it in fact has occurred. Power analysis is used to estimate the power of a given design and can provide insight into the sampling effort, both in terms of the number of samples and the number of years, required to observe trends of different sizes. In addition, power analyses can reveal important inherent constraints on the ability to detect trends imposed by underlying variability in the system being monitored. This can provide a realistic basis for establishing both management and monitoring goals, as well as a basis for making tradeoffs in the monitoring design (e.g., between the number of samples collected per year and the number of years over which the trend monitoring will extend).

In one instance, a power analysis may show that a trend will not be evident even after decades of monitoring at frequent intervals, and, therefore trend monitoring would be futile and monitoring resources should be shifted to another site and/or issue. In another instance, improving the sampling design's ability to detect a trend may require an increase in the number of years to be monitored. In this case, the length of time needed to detect a trend must be compared against both the management time horizon (i.e., how quickly is information needed?) and the timeframe over which changes are expected to occur (e.g., how rapidly are BMPs expected to reduce loads?). In a third instance, the main way to improve the design's power is to increase the number of samples collected per year. However, there is a natural constraint imposed by the relatively small number of storms per year in Riverside County. In such cases, the monitoring design will have an inherent limit on its ability to detect trends within a given time period. Sampling additional times per year and monitoring for more years must be traded off against each other, since increasing both kinds of sampling intensity improves power. Such tradeoffs should be based on the management time horizon, the timeframe over which changes are expected to occur, and the resources available to the Permittees.

The Stormwater Monitoring Coalition is developing Urban Runoff monitoring program guidance that will include a procedure in calculating statistical power. The Permittees will use the guidance to evaluate the statistical power of its current monitoring program design and that of the revised monitoring program as it is implemented. The results will be discussed in future Annual Reports.

APPENDIX A

WHITEWATER WATERSHED

APPENDIX B

SANTA ANA WATERSHED

1. INTRODUCTION

A MS4 Permit (Order No. R8-2002-0011, NPDES No. CAS618033) for the Santa Ana Watershed was adopted by the Santa Ana Regional Board on October 25, 2002. This permit establishes monitoring and reporting requirements for discharges from the MS4.

The development of the revised CMP was initiated following the adoption of the Order on October 25, 2002. To oversee this process, a Monitoring Subcommittee to the Santa Ana/Santa Margarita Technical Committee was established. The Monitoring Subcommittee was chaired by the District and included Co-Permittee representatives. Regional Board staff were noticed of each of these meetings.

The Order also required the development of an Interim Monitoring Program that focused on areas with elevated pollutant concentrations. In response, the Monitoring Subcommittee prepared an Interim Monitoring Program that proposed the removal of stations that did not serve the goals of an Urban Runoff monitoring program. The justifications for removal included:

- flows do not represent primarily urban land uses;
- flows consist primarily of produced water
- a majority of the drainage area and/or flow originates in another county;
- the station was sampled as part of a preliminary survey of the watershed and was never intended to be part of the CMP; and
- sediment samples were collected as part of a pilot program to test, remove, and properly dispose of sediment deposits accumulated in large detention and retention basins which may contain relatively high concentrations of pollutants.

Subsequent to submittal of the Interim Monitoring Program, the Monitoring Subcommittee continued to revise the CMP. A variety of information sources were utilized by the Monitoring Subcommittee, including land use, chemical and flow data from the District and other agencies, and comparison benchmarks. In addition, field inspections of existing and proposed monitoring station sites were conducted. All of this information was used in concert in selecting monitoring stations for inclusion in the Santa Ana Watershed element of the CMP.

The CMP, as well as this appendix, is intended to be a "living document," subject to revision based on changes in accessibility to the monitoring location, Permit requirements, and program guidance. Changes will undergo review by the Permittees and Regional Board staff before being incorporated into the CMP.

2. OBJECTIVES

According to the Urban Runoff Monitoring & Reporting Program (Appendix 3 of the MS4 Permit), the overall goal is to support the development of an effective Urban Runoff management program. The following are the major objectives (Section II of Appendix 3):

- To identify those Receiving Waters, which, without additional action to control Pollution from Urban Runoff, that cannot reasonably be expected to achieve or maintain applicable Water Quality Standards required to sustain the Beneficial Uses, the goals, and the objectives of the Basin Plan.
- To develop and support an effective MS4 management program.
- To identify significant water quality problems related to discharges of Urban Runoff within the Permit Area.

- To define water quality status, trends, and pollutants of concern associated with Urban discharges and their impact on the Beneficial Uses of the Receiving Waters.
- To analyze and interpret the collected data to determine the impact of Urban Runoff and/or validate any water quality models.
- To characterize pollutants associated with Urban Runoff, and to assess the influence of Urban land uses on Receiving Water quality and the beneficial uses of Receiving Waters.
- To identify other sources of Pollutants in storm water runoff to the maximum extent possible (e.g., including, but not limited to, atmospheric deposition, and contaminated sediments, other non-point sources, etc.)
- To identify and prohibit illicit connections and discharges.
- To verify and to identify sources of Urban Runoff pollutants.
- To evaluate the effectiveness of the DAMP and WQMPs, including an estimate of pollutant reductions achieved by the structural and nonstructural BMPs implemented by the Permittees.
- To conduct monitoring in cooperation with San Bernardino County for investigation of bacteriological impairments in the upper Santa Ana River due to Urban Runoff.
- To evaluate the costs and benefits of proposed Urban Runoff management programs to protect Receiving Water quality.

3. MONITORING PROGRAM REQUIREMENTS

The Monitoring Program has certain required elements, but there is flexibility in how the Permittees may implement them. The discussion that follows will present the Monitoring Program Requirements (Section III of Appendix 3) and will discuss how the CMP complies with the Requirement. For Program Requirements that are not part of the CMP, activities that will comply will be discussed.

- A. TMDL/303(d) Listed Waterbody Monitoring: The Permittees should continue to participate in the TMDL and Southern California Cooperative Storm Water Research/Monitoring programs as they relate to Urban Runoff. In addition, strategies shall be revised/developed to evaluate the impacts of Urban Runoff on identified impairments within the Santa Ana River watershed and other tributary 303(d) listed waterbodies.

The Permittees have been participating and will continue to participate in the San Jacinto River/Lake Elsinore Watersheds nutrient TMDL (Table B-2) and Chino Basin/Santa Ana River pathogen indicator TMDL (monitoring conducted by the City of Riverside). The Permittees also participate with the Southern California Stormwater Monitoring Coalition and have provided funds for specific studies, including a rapid microbiological indicator development, and a model Urban Runoff monitoring program to assist the SWRCB to partially fulfill SB72 requirements.

- B. 1. Mass Emissions Monitoring:

- a. An estimate of flow in cubic feet per second (cfs) from the outfall/stream at the time of sampling.

Flow is either estimated or measured when a sample is collected. The data are stored in the District's water quality database under parameter number 232 (water level) or 262 (discharge).

- b. Monitor mass emissions in Urban Runoff to: (a) estimate the total mass emissions from the MS4 to Receiving Waters; (b) assess trends in mass emissions associated with Urban Runoff over time; and (c) to determine if Urban Runoff is contributing to exceedences of Water Quality Objectives or Beneficial Uses in Receiving Waters by comparing results to the Basin Plan.

See Section 7.

- c. Representative samples from the first storm event and two more storm events shall be collected during the rainy season. A minimum of three dry-weather samples shall also be collected. Samples from the first rain event each year shall be analyzed for the entire suite of priority pollutants. All samples must be analyzed for metals, pH, TSS, TOC, pesticides/herbicides, and constituents that are known to have contributed to impairment of local receiving waters. Dry weather samples should also include an analysis for oil and grease. Sediments associated with mass emissions should be analyzed for constituents of concern identified in the water analyses.

See Sections 4.B.2) and 4.B.3).

Constituents of Concern, such as metals, that may be identified from the water quality data, will be analyzed in the sediments.

2. Microbial Monitoring: A monitoring program to determine the sources of bacteriological contamination in the Upper Santa Ana River, is being developed in collaboration with the MS4 Permittees in San Bernardino County. This program associated with Urban Runoff shall include wet and dry weather monitoring, as appropriate, for bacteriological constituents in the Santa Ana River and its tributaries.

On March 23, 2000, the Santa Ana Regional Board issued a 13267 directive for the Santa Ana Region Permittees to collaborate with the MS4 Permittees in San Bernardino County to develop a bacterial source identification study for the Santa Ana River. As a result, a draft study design was developed and monitoring was initiated at the stations identified in Table B-3. The San Bernardino County submitted the draft study design with to fulfill their MS4 Permit requirements, and the Riverside County Permittees intended to do the same in conjunction with this CMP.

On October 15, 2003, Riverside County Permittees were made aware of a study, to be conducted by Dr. Stanley Grant of UC Irvine, to evaluate the dynamics of point and non-point source fecal pollution in the Santa Ana River. The study is expected to produce:

- *Information on the sediment and water column ecology of fecal indicator bacteria (FIB) (specifically speciation and microbial diversity) in an Urban watershed under both dry and wet weather conditions.*
- *Information on the temporal variability of in-stream FIB concentrations and loading, and the effect of both local and external forcing.*
- *A mathematical model for predicting FIB concentrations (and loads) in Urban streams that captures the dominant ecological and transport phenomena identified during the field phase of the project.*

The study will be among the first to investigate how storm flows affect the ecology of FIB microbial populations in ephemeral watersheds.

Section XIV of the MS4 Permit (Page 52) allows "the Permittees to participate in regional, statewide, national or other monitoring and reporting programs in lieu of or in addition to" the Monitoring Program. In lieu of the Monitoring Program requirement, and in collaboration with San Bernardino County Permittees, the Riverside County Permittees will contribute funds to participate in Dr. Grant's study.

The details of the study are available in a separate document.

3. Water Column Toxicity Monitoring: Analyses for toxicity to aquatic species shall be performed on Receiving Water samples to determine the impacts of Urban Runoff on toxicity of Receiving Waters. *Ceriodaphnia dubia* fertilization, Fathead Minnow larval survival test, and Selenastrum Capricornutum growth test shall be used to evaluate toxicity on the sample from the first rain event, plus one other wet weather sample. In addition, where applicable collect two dry weather samples or propose equivalent procedures in the CMP. In addition, criteria shall be identified which will trigger the initiation of Toxicity Identification Evaluations (TIEs) and Toxicity Reduction Evaluations (TRES).

See Section 4.C. EPA freshwater toxicity guidance does not contain a protocol for Ceriodaphnia dubia fertilization. It does, however, contain a protocol for Ceriodaphnia dubia reproduction. Pursuant to an e-mail letter sent on December 3, 2003, by Regional Board staff to the Permittees, the reproduction test will be substituted.

4. Reconnaissance: The Permittees shall review and update their reconnaissance strategies to identify and prohibit illicit discharges. Where possible, the use of GIS to identify geographic areas with a high density of industries associated with gross pollution (e.g. electroplating industries, auto dismantlers) and/or locations subject to maximum sediment loss (e.g. new development) may be used to determine areas for intensive monitoring efforts. Additionally, the Permittees shall coordinate with the Regional Board to develop a comprehensive database to include enforcement actions for storm water violations and unauthorized, non-storm water discharges that can then be used to more effectively target reconnaissance efforts.

See Section 4.A.

5. Land Use Correlations: The Permittees shall develop and implement strategies for determining the effects of Urban land use on the quality of Receiving Waters. While it is recognized that a wide range of land uses exist across the region and within each sub-watershed, one relationship that may be determined is the impact of Urban development on sediment loading within Receiving Waters, since developed areas contribute relatively little sediment loading compared to areas under construction. Consequently, the Permittees shall, at a minimum, analyze the impacts of increasing development and the conversion of agricultural land to Urban land uses to the sediment loading of Canyon Lake, Lake Elsinore, and the Santa Ana River (Reaches 3 and 4).

See Section 7.

6. Sources of Data: Where possible and applicable, data shall be obtained from monitoring efforts of other public or private agencies/entities (e.g., Caltrans).

See Section 7.

7. Bioassessments: The development of an Index of Biological Integrity for Southern California. This shall include the selection and identification of appropriate bioassessment station locations, sampling scheme(s), and shall also be capable of attaining the objectives mentioned in Section II (of Permit, Section 2 of this Appendix), above. The Permittees may develop bioassessments in coordination or cooperation with other parties...

In lieu of developing an independent bioassessment program, the Permittees will be contributing \$25,000 towards a regional bioassessment study ("Building a Regionally Consistent and Integrated Freshwater Stream Bioassessment Monitoring Program") being spearheaded by SCCWRP and including the counties of Los Angeles, Orange, San Bernardino, San Diego, and Ventura, and the Santa Ana, San Diego, and Los Angeles Regional Boards.

- C. ...At a minimum, the CMP shall address the following and any requirements developed by the State Board in accordance with Water Code Section 13383.5:

1. Uniform guidelines for quality control, quality assurance, data collection and data analysis.

See Section 6.

2. A procedure for the collection, analysis, and interpretation of existing data from local, regional or national monitoring programs. These data sources may be utilized to characterize different sources of pollutants discharged to the MS4; to determine pollutant generation, transport and fate; to develop a relationship between land use, development size, storm size and the event mean concentration of pollutants; to determine spatial and temporal variances in Urban Runoff quality and seasonal and other bias in the collected data; and to identify any unique features of the Permit Area. The Permittees are encouraged to use data from similar studies, if available.

See Section 7.

3. A description of the CMP including:

- a. The number of monitoring stations;

See Table B-1 for Core CMP stations (7), Table B-2 for San Jacinto nutrient TMDL stations (14), and Table B-3 for current Santa Ana River bacterial indicator study stations (3). The bacterial indicator study will be changing (See B.2. above).

- b. Monitoring locations within MS4s, major outfalls, and Receiving Waters; Environmental indicators (e.g., ecosystem, flow, biological, habitat, chemical, sediment, stream health, etc.) chosen for monitoring;

See Tables B-1, B-2, and B-3.

- c. Total number of samples to be collected from each station, frequency of sampling during wet and dry weather, short duration or long duration storm events, type of samples (grab, 24-hour composite, etc.), justification for composite versus discrete sampling, type of sampling equipment, quality assurance/quality control procedures followed during sampling and analysis, analysis protocols to be followed (including sample preparation and maximum reporting limits), and qualifications of laboratories performing analyses;

See Table B-4.

- d. A procedure for analyzing the collected data and interpreting the results including an evaluation of the effectiveness of the management practices, and need for any refinement of the WQMPs or the DAMP.

See Section 7.

- e. Parameters selected for field screening and for laboratory work; and

See Section 4.A.2)

- f. A description of the responsibilities of all the participants in this program, including cost sharing.

The current Implementation Agreement is being reviewed and will be updated.

Table B-1. Core CMP Stations in the Santa Ana Watershed

Station Number	Station Name	Notes	Land Uses in Drainage Area			Gauge Costs
			Land Use	Acres	Percent

SANTA MARGARITA WATERSHED

APPENDIX D

WATER QUALITY PARAMETERS THAT MAY BE MONITORED

The following parameters may have a Basin Plan Objective (BPO) comparison benchmark. A description of the parameter's importance to Urban Runoff water quality and the types of industries likely to discharge it in their waste stream are also included. This information is largely taken from Water Quality Criteria, 2nd Edition. This list does not include all parameters on EPA's Priority Pollutant list.

Alkalinity, Total (CaCO₃) (Hydron #1035)

Alkalinity measures the ability of a solution to neutralize hydrogen ions and is expressed in terms of an equivalent amount of calcium carbonate. Alkalinity may indicate the presence of carbonates, bicarbonates, hydroxides, and to a lesser extent borates, silicates, phosphates, and organic substances. Waters with pH values between 7 and 8 and having a total alkalinity of 100 to 120 mg/L or more serves as a buffer to help prevent any sudden change in pH value, which could harm fish and other aquatic life. Some natural waters, especially those in the southwestern U.S., are highly alkaline. The alkalinity of streams can also be increased by the addition of municipal sewage and many industrial wastes.

Ambient Air Temperature (#1017, °C; #1018, °F)

Air temperature can affect water temperature, which can, in turn affect the concentration of dissolved oxygen. Drinking water standards for fluoride are based on maximum daily air temperatures.

Ammonia-nitrogen (#1051)

Ammonia may be found naturally in surface or ground waters from the decomposition of nitrogenous organic matter, being one of the constituents of the complex nitrogen cycle. Rivers known to be unpolluted have very low ammonia concentrations, generally less than 0.2 mg/L as N. Ammonia may be discharged in industrial wastes. Ammonia is also a component of fertilizer and urine, and its presence may indicate agricultural use or overapplication in domestic and recreational areas.

Antimony (#1065)

This silvery-white metal is seldom found in the pure state in nature. Antimony is used for alloys and other metallurgical purposes. The salts, primarily sulfides and oxides, are employed in the rubber, textile, fireworks, paint, ceramic, and glass industries.

Arsenic (#1070)

Elemental arsenic may be found to a small extent in nature mostly as the arsenides of true metals or pyrites. Its major use, however, is as a component of pesticides (insects, weeds, fungi) and as a wood preservative.

Bacteria; Fecal coliforms (#1075)

Bacteria; Total coliforms (#1085)

Coliform organisms originate in excretions from humans, mammals, amphibians, and birds. They are also found, primarily in the non-fecal forms on fibrous and vegetable matter in the water. More coliforms are discharged by healthy individuals than by sufferers of diarrhea.

Bacteria; Fecal streptococci (#1080)

Fecal streptococci is considered a useful indicator of potential pathogen contamination by intestinal wastes as this group of bacteria is characteristic of fecal pollution, they do not multiply in surface waters, and they rarely occur in surface soil or on vegetation (unless contaminated by sewage). Primary sources of bacteria include agricultural drainage, feeding pens, grazing areas, and sanitary sewer and septic tank leaks.

Barium (#1090)

Barium is not normally present in natural surface or ground waters. Industrial uses of barium and its salts include metallurgy, paint manufacturing, cement production (for mixtures designed to withstand salt water), and in ceramic and glass manufacturing.

Beryllium (#1120)

Beryllium is relatively rare and not likely to occur in natural waters. Industrial uses of beryllium include metallurgy, manufacturing of X-ray diffraction tubes and electrodes for neon signs, and nuclear reactors.

Bicarbonate (HCO₃) (#1125)

Bicarbonates contribute to the alkalinity of water, or the capacity of water to neutralize acids. Bicarbonates have many natural and industrial sources. Natural sources include absorption of carbon dioxide from the air and the decomposition of organic materials. Bicarbonates are one of the most commonly used salts in industry. Bicarbonates are not generally considered environmentally harmful, but can add to the salinity and total solids content of water.

Boron (#1135)

Boron in nature is found as sodium borate (borax) or as calcium borate (colemanite) in mineral deposits and natural waters of Southern California and in Italy. Industrial uses of boron, boron salts, or boric acid include metallurgy (to harden metals), weatherproofing of wood, fireproofing fabrics, glass and porcelain manufacturing, production of leather and carpets, cosmetics, photography, and artificial gems, and as a bactericide, fungicide, or detergent.

Cadmium (#1145)

Cadmium has many industrial uses, including metallurgy, electroplating, ceramics, pigmentation, photography, textile printing, and nuclear reactors. Cadmium salts are sometimes employed as insecticides and antihelminthics. Cadmium can concentrate in the liver, kidneys, pancreas, and thyroid of humans and animals, and tends to persist.

Calcium (#1150)

Calcium is typically found as a salt or in the ionic form. Natural sources include leaching from soil or decomposition of skeletal remains. They may also be found in sewage and many types of industrial wastes.

Carbon, total organic (TOC) (#1155)

Organic carbon is not in itself a pollutant, but is an indicator of pollution and benthic deposits. In the TOC test, the carbon in the sample is oxidized by dichromate or another strong oxidizing agent.

Carbonate (CO₃) (#1160)

Carbonate concentration in water is a function of temperature, pH, cations, and other dissolved salts. Carbonate salts may be removed from polluted waters by precipitation and adsorption

Chloride (#1165)

Natural sources of chlorides include dissolution from minerals or seawater intrusion. Industrial sources include agricultural use, human and animal sewage, paper manufacturing, galvanizing plants, water softening plants, oil wells, and petroleum refineries. Chlorine is a commonly-used disinfectant in water treatment.

Chlorpyrifos (#1178)

No info

Chromium, all valences (#1180)

Chromium wastes occur mostly in the hexavalent form. Industrial sources of hexavalent chromium include metal pickling and plating operations, aluminum anodizing, leather tanning, cooling water antifouling, and in the manufacture of paints, dyes, explosives, ceramics, and paper. Industrial sources of trivalent chromium salts include textile dyeing, ceramic and glass manufacturing, and in photography.

Color (#1195)

There are numerous natural sources of color in water including breakdown of minerals (especially those containing iron or manganese compounds) or vegetable matter, humus, peat, tannins, algae, weeds, and protozoa. Industrial sources include irrigation return water, nailworks, mining, refining, and manufacture of explosives, pulp and paper, and chemicals. It can be expected that waters flowing through erodible soils, such as those found in the Santa Margarita River Watershed, will have a detectable color concentration.

Conductance, specific (#1200, field; #1205, lab)

Specific conductance measures the ion concentration of water. Increased conductivity increases the osmotic pressure of water, which can be harmful to aquatic organisms. Natural inland waters usually contain small quantities of mineral salts in solution, but waters containing brine, chemical, and agricultural irrigation wastes may have excessive levels of specific conductance.

Copper (#1210)

Copper salts are not commonly found in natural surface waters. Industrial sources of copper include corrosion of copper and brass tubing, copper compounds used to control undesirable plankton organisms, alloy production, electrical wiring, pipes, roofing, and many purposes where its conductivity or corrosion resistance are important. Copper salts are used in textile processing, pigmentation, tanning, photography, engraving, electroplating, insecticides, fungicides, and many other industrial processes.

Cyanide, total (#1215)

Cyanides may be found in effluents from gas works and coke ovens, from the scrubbing of gases at steel plants, from metal cleaning and electroplating processes, and from chemical industries.

Detergent – MBAS (#1225)

Surface-active agents such as soaps, detergents, emulsifiers, wetting agents, and penetrants lower the surface tension or other interfacial properties of their solvents. This allows dirt to be removed from clothing and for greater absorption of pesticides into their target organisms.

Diazinon (#1227)

Diazinon is commonly-used insecticide.

Discharge (#262)

Also known as the flow rate, high discharge rates may cause erosion in an earthen channel. Used along with chemical concentration to calculate mass loading.

Electrochemical Balance (#1235) No BPO

If positive, there are more cations than anions in the sample, and if negative, there are more anions.

Fluoride (#1255)

Fluoride may be found in natural waters, its value in preventing tooth decay being based on observations that people living in areas with elevated levels had lower rates of tooth decay. Industrial sources of fluoride include insecticide manufacture and use, brewery apparatus disinfection, as a flux in steel manufacturing, wood and mucilage preservation, glass and enamel manufacturing, chemical industries,

and for water treatment. It not normally found in industrial wastes. Drinking water standards are based on maximum daily air temperatures.

Hardness, total (CaCO₃) (#1265)

Hardness in water may be caused by the natural accumulation of salts (primarily calcium and magnesium ions) from contact with soil and geological formations. Industrial sources include tannery wastes and irrigation return flows. Imported water may also be a source of elevated hardness levels, for example, Colorado River Water has an average hardness of 250-300 mg/L, which is considered hard water.

Hydrocarbons, total petroleum (#1270)

Industrial sources of petroleum hydrocarbons include those involved in the production, transportation, handling, and use of oil, such as oil wells, oil-loading points, refineries, railroads, civic dumps, salvage dumps, and garages.

Hydroxide (OH) (#1275)

Hydroxides contribute to the alkalinity of water. It is not present in to an appreciable degree in natural waters. Industrial sources of hydroxide includes tanneries, soda and sulfate pulping mills, and textile mills.

Iron (#1285)

Iron may be found naturally from the corrosion of iron in mineral deposits and iron-bearing ground water. Industrial sources include pickling operations, acid-mine drainage, and corrosion from iron pipes and other materials.

Lead (#1290)

Lead is a harmful substance that can lead to neurological damage. Natural sources of lead in water include leaching from mountain limestone and galena. Industrial sources of lead include mining effluents, use in solder in electronics and piping.

Level (# 232)

In a well-defined channel, the water level, along with the rating curve, can be used to calculate the flow rate.

Magnesium (#1300)

Magnesium ions are present in significant concentrations in natural waters, and along with calcium form the bulk of the hardness reaction. Industrial sources of magnesium include light alloy and other metallurgical production, and in the manufacture of electrical and optical apparatus.

Manganese (#1305)

Manganese ions are rarely found in natural surface waters above a concentration of 1.0 mg/L. Industrial sources of manganese include manufacture of steel alloys, dry-cell batteries, glass and ceramics, paints and varnished, inks and dyes, matches and fireworks, and in agriculture to enrich manganese-deficient soils.

Mercury (#1310)

Mercury can appear in the metallic state in some natural waters, but the ionic form is most harmful to aquatic life. Industrial sources of mercury include use in scientific and electrical instruments, in dentistry, in power generation, in solders, in the manufacture of lamps and batteries, and in the improper disposal of thermostat switches and old thermometers and manometers.

Nickel (#1320)

Nickel as a pure metal it is not a problem as it is not soluble in water. Many nickel salts, however, are highly soluble in water. Industrial uses of nickel salts include the metal-plating industry.

Nitrogen, Nitrate (N) (#1340)

Nitrates are an essential fertilizer for plant life, and are therefore rarely found in natural surface waters at high concentrations. Nitrates may also be present in groundwaters as a result of excessive application of fertilizer or cesspool or septic tank leachate. Industrial uses of nitrogen include chemical fertilizer production, field application of fertilizer, livestock sewage, and irrigated agriculture.

Nitrogen; Nitrite (N) (#1345)

Nitrites are usually quickly oxidized to nitrates by bacterial action in natural waters and are therefore seldom found at significant concentrations. The presence of nitrite alone does not always signify the presence of pollution, but in conjunction with ammonia and nitrate, often indicate pollution.

Nitrogen; Organic (N) (#1350)

No info

Nitrogen; Total (N) (#1355)

Nitrogen is present in natural and polluted waters as ammonia, organic nitrogen, nitrites, and nitrates. The total concentration of nitrogen is not as important as the form in which it exists. Organic nitrogen, amino acids, and ammonia may inhibit biological growth whereas nitrates stimulate phytoplankton. Industrial sources of the various components of total nitrogen are discussed under their proper headings.

Nitrogen; total inorganic (N) (#1365)

No info

Nitrogen; total Kjeldahl (N) (#1360)

No info

Nitrogen; un-ionized ammonia (N) (#1370)

No info

Odor (#1375)

Natural sources of odor in water include living microscopic organisms and decaying vegetation, including weeds, bacteria, fungi, actinomycetes, algae, and decaying organic matter. Industries that may generate odor-causing wastes include: pulp and paper; explosives; petroleum, gasoline, and rubber; wood distillation; coke and coal tar; gas; tanneries, meat-packing and glue; chemicals and dyes; and milk products, canneries, beet-sugar, distillation and other food products.

Odor is reported in terms of "threshold odor number" (TON) which is calculated from the amount of sample in the most diluted portion giving perceptible odor. The threshold odor number equals the volume of the dilution divided by the volume of the sample in the dilution.

It is frequently difficult, if not impossible, to identify the specific cause of an odor or taste, as many substances may cause what appears to be the same effect, or because mixtures of substances may be involved. Among the chemicals responsible for tastes and odors are halogens, sulfides, ammonia, turpentine, phenols and cresols, picrates, various hydrocarbons and unsaturated organic compounds, mercaptans, tar and tar oils, detergents, pesticides, and innumerable others, many of unknown identity. Hydrocarbons may be a major source of taste and odors in water.

Oil & Grease (#1380)

Oil and grease in water may coat aquatic life and create undesirable odors. Industrial sources of oil and grease include all aspects of the petroleum industry, packing plants, slaughter houses, rendering plants, cotton seed processing plants, textile mills, milk-processing plants, chemical works, machining operations, and garages.

Organic matter (%) (#1384)

No info

Organics; BNA extractible (625) (#1385)

No info

Organics; purgeable halocarbons (624) (#1410)

No info

Oxygen Demand, Biochemical (BOD) (#1425)

In itself, BOD is not a pollutant and does not directly cause environmental harm. When dissolved oxygen is depressed to harmful levels, BOD will indirectly exacerbate the effects of diminished oxygen. BOD does not indicate the presence of a single substance, but measures the effect of a combination of substances and conditions.

Oxygen Demand, Chemical (COD) (#1430)

The COD test measures the organic strength of domestic, agricultural, and industrial wastes, but it does not differentiate between the biologically oxidizable (could be taken up by fish and plants) and biologically inert organic matter.

Oxygen, dissolved (#1435)

Dissolved oxygen concentration is a function of the temperature and salinity of the water. Increasing temperature or salinity results in a decreasing oxygen-holding capacity of water. Dissolved oxygen is not constant in a natural system, as organisms, chemical reactions, and physical conditions use or generate oxygen at various rates. As dissolved oxygen levels decrease, aquatic life suffers or dies, and in the absence of oxygen, anaerobic decomposition may lead to unfavorable odors and colors in the water.

Oxygen; field saturation (#1445)

No info

pH (#1705, field; #1710, lab)

pH is not a pollutant in itself, but an indicator of pollution. Natural waters and treated sewage is usually neutral or slightly alkaline, but many industrial wastes are strongly acidic or alkaline. Acid wastes include tan liquors, acid dyes, coal-mine drainage, sulfite waste liquors, pickling liquors, and some brewery wastes. Alkaline wastes include soda- and sulfate-pulp rinse waters, laundry wastes, and bottle wash waters.

Phenols (#1460)

Phenols are widely used as disinfectants, in the manufacture of synthetic resins, medical, and industrial compounds, and as a reagent for chemical analyses. Sources of phenolic wastes include the distillation of wood, coke ovens, oil refineries, chemical plants, sheep dips, and human and animal refuse.

Phosphorus, organic (P) (#1475)

No info

Phosphorus, ortho (P) (#1480)

No info

Phosphorus, total (P) (#1485)

Phosphorus in nature is found in the form of phosphates in several minerals and it is a constituent of fertile soils, plants, and the protoplasm, nervous tissue and bones of animal life. It is an essential nutrient for plant and animal growth. Excessive phosphorus leads to an overabundance of algae growth.

Phosphorus, total dissolved (P) (#1490)

No info

Phosphorus, total insoluble (P) (#1495)

No info

Potassium (#1500)

Potassium is commonly found in fertilizers.

Redox Potential (mV) (#1515)

No info

Salinity (ppt) (#1518)

Inland waters typically contain low levels of dissolved mineral salts, but brines and various chemical wastes may increase salinity to levels harmful to living organisms because of the increase in osmotic pressure.

Selenium (#1520)

Selenium is found in some soils as ferric selenite or calcium selenate. It may also be found in decayed plant tissue. Industrial sources of selenium include pigmentation in paints, dyes, and glass production; as a component of rectifiers, semiconductors, photo-electrical cells, and other electrical apparatus; as a supplement to sulfur in the rubber industry; as a component of alloys; and for insecticide sprays. Selenium may also be found in the municipal sewage from industrial communities.

Silver (#1535)

Industrial sources of silver include manufacture of jewelry and silverware, in alloys, for electroplating, and in the processing of food and beverages. Silver nitrate is used in photography, ink manufacture, electroplating, coloring porcelain, and as an antiseptic.

Sodium (#1540)

Sodium salts are extensively found in nature and in industrial and agricultural wastes. As most sodium salts are extremely soluble in water, any sodium that is leached from soil or discharged to streams will remain in solution.

Solids, total (#1615, mg/l; #1616, %)

Solids in water are classified as either "dissolved" (capable of passing through a laboratory filter) or "suspended," (retained on the filter). Both dissolved and suspended solids may be differentiated further as "fixed" (inorganic) and "volatile" (organic or volatile material). It is the nature of the solids in water that may indicate a pollutant, not the presence of the solids themselves.

Solids, total dissolved (#1625)

In natural waters the dissolved solids consist mainly of carbonates, bicarbonates, chlorides, sulfates, phosphates, and possibly nitrates of calcium, magnesium, sodium, and potassium, with traces of iron,

manganese and other substances. Sources of dissolved solids include chemical wastes, dissolved salts, acids, alkalis, gas and oil-well brines, or drainage waters from irrigated land.

Solids, total suspended (#1630)

In natural waters, suspended solids consist normally of erosion silt, organic detritus, and plankton. Sources of suspended solids include industrial and domestic wastes, increased erosion from cleared or cultivated land, gravel washings and mine tailings, steel mill wastes, and dusts that are blown into streams.

Sulfate (SO₄) (#1640)

Sulfates occur in waters of the western United States as a result of leachings from gypsum and other common minerals. Other natural sources include oxidized organic matter. Industrial sources include agricultural runoff, tanneries, sulfate-pulp mills, textile mills, and other plants that use sulfates or sulfuric acid.

Sulfide (S⁻) (#1645)

Sulfides may be found in natural waters from anaerobic decomposition of organic matter. Sewage may also contribute sulfide. Industrial sources of sulfides include tanneries, paper mills, chemical plants, and gas works

Temperature, field (#1655, deg. C; #1660, deg. F)

Water temperature in natural waters is influenced by ambient temperature, vegetative cover, nature of bed material (*e.g.*, gravel vs. sand), and stream depth. Many industrial and agricultural wastes lead to raising of water temperatures, as does concrete-lining of streams. Increased water temperature may result in decreased oxygen capacity, generation of anaerobic zones, and fungal growth.

Thallium (#1665)

Thallium salts are used as poisons for rodents, as ant bait, and are used in dyes and pigments in fireworks, in optical glass, and as a depilatory.

Total Anions (#1675)

No info

Total Cations (#1680)

No info

Turbidity (#810; #1690, field; #1695, lab)

The turbidity of a water sample is a measure of the extent to which the intensity of light passing through is reduced by the suspended matter. Turbidity in water is attributable to suspended and colloidal matter, which diminishes light penetration. Increased turbidity may also indicate the presence of pathogens. Natural sources of turbidity include microorganisms or organic detritus; silica or other mineral substances including zinc, iron, and manganese compounds; and clay or silt. Erosion may also lead to increased turbidity as well as domestic sewage and industrial wastes, such as mining, dredging, logging, and pulp and paper manufacturing.

Zinc (#1700)

Industrial sources of zinc and zinc salts include galvanizing, alloy manufacture, for electrical purposes, in printing plates, dye manufacture and the dyeing process, paint pigments, cosmetics, pharmaceuticals, dyes, and insecticides.

APPENDIX E

GLOSSARY

Basin Plan - Water Quality Control Plan developed by a Regional Board..

CMP - Consolidated Program for Water Quality Monitoring

Conditions of Concern - Scour, erosion (sheet, rill and/or gully), aggradation (raising of a streambed from sediment deposition), changes in fluvial geomorphology, hydrology and changes in aquatic ecosystem.

Co-Permittees -

In the Whitewater Region: County of Riverside and the Cities of Banning, Cathedral City, Coachella, Desert Hot Springs, Indian Wells, Indio, La Quinta, Palm Desert, Palm Springs, Rancho Mirage, and the Coachella Valley Water District.

In the Santa Ana Region: County of Riverside and the Cities of Beaumont, Calimesa, Canyon Lake, Corona, Hemet, Lake Elsinore, Moreno Valley, Murrieta, Norco, Perris, Riverside, and San Jacinto.

In the Santa Margarita Region: County of Riverside and the Cities of Murrieta and Temecula.

County - County of Riverside, legal entity

CWA - Federal Clean Water Act

GIS - Geographical Information Systems.

"illegal discharge" - Illegal discharge means any disposal, either intentionally or unintentionally, of material or waste to land or MS4s that can pollute storm water or create a nuisance. The term illegal discharge includes any discharge to the MS4 that is not composed entirely of storm water, except discharges pursuant to an NPDES permit, discharges that are identified in the MS4 Permit, and discharges authorized by a Regional Board Executive Officer.

"illicit connection" - Illicit Connection means any connection to the storm drain system that is prohibited under local, state, or federal statutes, ordinances, codes, or regulations. The term illicit connection includes all non storm-water discharges and connections except discharges pursuant to an NPDES permit, discharges that are identified in the MS4 Permit, and discharges authorized by the Executive Officer.

Impaired Waterbody - Section 303(b) of the CWA requires each of California's Regional Water Quality Control Boards to routinely monitor and assess the quality of waters of their respective regions. If this assessment indicates that beneficial uses are not met, then that waterbody must be listed under Section 303(d) of the CWA as an impaired waterbody. The 1998 water quality assessment listed a number of waterbodies within the three Permit Areas as impaired pursuant to Section 303(d).

In the Whitewater Region:

Water Body Name	TMDL Priority	Estimated Size Affected	Unit	Pollutant_Stressor	Potential Sources	Proposed TMDL Completion
Coachella Valley Storm Channel	Medium	69	Miles	Pathogens	Source Unknown	

In the Santa Ana Region:

Water Body Name	TMDL Priority	Estimated Size Affected	Unit	Pollutant_Stressor	Potential Sources	Proposed TMDL Completion
Canyon Lake (Railroad Canyon Reservoir)	Low	453	Acres	Nutrients	Nonpoint Source	
Canyon Lake (Railroad Canyon Reservoir)	Low	453	Acres	Pathogens	Nonpoint Source	
Elsinore, Lake	High	2431	Acres	Unknown Toxicity	Unknown Nonpoint Source	2004
Elsinore, Lake	High	2431	Acres	Nutrients	Unknown Nonpoint Source	2003
Elsinore, Lake	High	2431	Acres	Sedimentation/Siltation	Urban Runoff/Storm Sewers	2003
Elsinore, Lake	High	2431	Acres	Organic Enrichment/Low Dissolved Oxygen	Unknown Nonpoint Source	2004
Santa Ana River, Reach 3	High	26	Miles	Pathogens	Dairies	2004
Santa Ana River, Reach 4	Low	14	Miles	Pathogens	Nonpoint Source	

In the Santa Margarita Region:

Water Body Name	TMDL Priority	Estimated Size Affected	Unit	Pollutant_Stressor	Potential Sources	Proposed TMDL Completion
Murrieta Creek	Low	12	Miles	Phosphorus	Urban Runoff/Storm Sewers	
Murrieta Creek	Low	12	Miles	Phosphorus	Unknown Nonpoint Source	
Murrieta Creek	Low	12	Miles	Phosphorus	Unknown point source	
Santa Margarita River (Upper)	Low	18	Miles	Phosphorus	Urban Runoff/Storm Sewers	
Santa Margarita River (Upper)	Low	18	Miles	Phosphorus	Unknown Nonpoint Source	
Santa Margarita River (Upper)	Low	18	Miles	Phosphorus	Unknown point source	

MS4 (Municipal Separate Storm Sewer System) – An MS4 is a conveyance or system of conveyances (including roads with drainage systems, municipal streets, catch basins, curbs, gutters, ditches, natural drainage features or channels, modified natural channels, man-made channels, or storm drains): (i) Owned or operated by a State, city town, borough, county, parish, district, association, or other public body (created by or pursuant to State law) having jurisdiction over disposal of sewage, industrial wastes, storm water, or other wastes, including special districts under State law such as a sewer district, flood control district or drainage district, or similar entity, or an Indian tribe or an authorized Indian tribal organization, or designated and approved management agency under section 208 of the CWA that discharges to Waters of the U.S.; (ii) Designated or used for collecting or conveying storm water; (iii) Which is not a combined sewer; (iv) Which is not part of the POTW as defined at 40 CFR 122.2.

Historic and current developments make use of natural drainage patterns and features as conveyances for Urban Runoff. Urban streams used in this manner are part of the municipalities MS4 regardless of whether they are natural, man-made, or partially modified features. In these cases, the urban stream is both an MS4 and a receiving water.

"non-point source" - Non-point source refers to diffuse, widespread sources of pollution. These sources may be large or small, but are generally numerous throughout a watershed. Non-point sources, include but are not limited to urban, agricultural or industrial area, roads, highways, construction sites, communities served by septic systems, recreational boating activities, timber harvesting, mining, livestock grazing, as

well as physical changes to stream channels, and habitat degradation. Non-point source pollution can occur year round any time rainfall, snowmelt, irrigation, or any other source of water runs over land or through the ground, picks up pollutants from these numerous, diffuse sources and deposits them into rivers, lakes and coastal waters or introduces them into ground water.

"non-storm water" – Non-storm water consists of all discharges to and from a storm water conveyance system that do not originate from precipitation events (i.e., all discharges from a conveyance system other than storm water). Non-storm water includes illicit discharges, non-prohibited discharges and NPDES permitted discharges. An illicit discharge is defined at 40 CFR 122.26(b)(2) as any discharge to a MS4 that is not composed entirely of storm water except discharges pursuant to a separate NPDES permit and discharges resulting from emergency fire fighting activities.

NPDES (National Pollutant Discharge Elimination System) – Permits issued under Section 402(p) of the CWA for regulating discharge of pollutants to Waters of the U.S.

"nuisance" – As defined in the Porter-Cologne Water Quality Control Act a nuisance is "anything which meets all of the following requirements:

- 1) Is injurious to health, or is indecent, or offensive to the senses, or an obstruction to the free use of property, so as to interfere with the comfortable enjoyment of life or property.
- 2) Affects at the same time an entire community or neighborhood, or any considerable number of persons, although the extent of the annoyance or damage inflicted upon individuals may be unequal.
- 3) Occurs during, or as a result of, the treatment or disposal of wastes."

Order

In the Whitewater Region: Order No. 01-077 (NPDES No. CAS617002)

In the Santa Ana Region: Order No. R8-2002-0011 (NPDES No. CAS618033)

In the Santa Margarita Region: Order No. 98-02 (NPDES No. CAS0108766), currently in revision.

Permit Area -

In the Whitewater Region: "The urbanized areas that lie approximately between the San Gorgonio Pass area to the northwest and the Salton Sea to the southeast. The majority of this area is in the Coachella Valley. The generally northwest-southeast trending Coachella Valley is in the northern portion of a large low area in the Colorado Desert known as the Salton Basin with major drainage to the Salton Sea. The San Jacinto Mountains bound the Coachella Valley on the southwest, and the San Gorgonio Mountains, Indio Hills and Mecca Hills bound the Coachella Valley on the northeast side. Major drainage is through the Whitewater River, and its tributaries, which reach the northern end of the Salton Sea. The headwaters of the Whitewater River originate from Mt. San Gorgonio. The valley surface is characterized as wide, boulderly, alluvial fans and sand dunes."

In the Santa Ana Region: "The portion of the Santa Ana River Watershed that is within the County of Riverside and identified on Appendix 1 as 'Urban Area' and those portions of 'Agriculture' and 'Open Space', as identified on Appendix 1, that do convert to industrial, commercial, or residential use during the term of the Order."

In the Santa Margarita Region: "The permitted area is delineated by the Santa Ana RWQCB-SDRWQCB boundary line on the north, the SDRWQCB-Colorado River Basin RWQCB boundary line on the east, and the County of Riverside boundary line on the south and west."

Permittees - Co-Permittees and the Principal Permittee

"point source" – Any discernible, confined, and discrete conveyance, including, but not limited to, any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operations, landfill leachate collection systems, vessel, or other floating craft from which pollutants are or may be discharged.

"pollutant" – A pollutant is broadly defined as any agent that may cause or contribute to the degradation of water quality such that a condition of pollution or contamination is created or aggravated.

Pollutants of Concern – A list of potential pollutants to be analyzed for in the Monitoring and Reporting Program. In developing this list, consideration should be given to the chemicals and potential pollutants available for storm water to pick-up or transport to Receiving Waters, all pollutants for which a waterbody within the Permit Area that has been listed as impaired under CWA Section 303(d), the category of development and the type of pollutants associated with that development category.

"pollution" – As defined in the Porter-Cologne Water Quality Control Act, pollution is the alteration of the quality of the Waters of the U.S. by waste, to a degree that unreasonably affects either of the following: A) the waters for beneficial uses; or 2) facilities that serve these beneficial uses. Pollution may include contamination.

POTW – Publicly-Owned Treatment Works

Principal Permittee - Riverside County Flood Control and Water Conservation District.

Rainy Season – October 1 through May 31st of each year.

RCFC&WCD - Riverside County Flood Control and Water Conservation District

"receiving water(s)" – The Waters of the U.S. that includes surface and ground waters.

Receiving Water(s) - The receiving waters within the Permit Area

Receiving Water Limitations – Receiving Water Limitations are requirements included in Orders issued by a Regional Board to assure that the regulated discharges do not violate water quality standards established in the Basin Plan at the point of discharge to Waters of the U.S. Receiving Water Limitations are used to implement the requirement of CWA section 301(b)(1)(C) that NPDES permits must include any more stringent limitations necessary to meet water quality standards.

Receiving Water Quality Objectives - Water quality objectives specified in a Basin Plan for Receiving Waters.

Region

In the Whitewater Region: Whitewater River Watershed within Riverside County and within the Principal Permittee's jurisdiction.

In the Santa Ana Region: Santa Ana River Watershed within Riverside County

In the Santa Margarita Region: Santa Margarita River Watershed within Riverside County

Regional Board

In the Whitewater Region: California Regional Water Quality Control Board, Colorado River Region

In the Santa Ana Region: California Regional Water Quality Control Board, Santa Ana Region

In the Santa Margarita Region: California Regional Water Quality Control Board, San Diego Region

Riverside County - Territory within the geographical boundaries of the County.

"sediment" – Soil, sand, and minerals washed from land into water. Sediment resulting from anthropogenic sources (i.e. human induced land disturbance activities) is considered a pollutant. This Order regulates only the discharges of sediment from anthropogenic sources and does not regulate naturally occurring sources of sediment. Sediment can destroy fish-nesting areas, clog animal habitats, and cloud waters so that sunlight does not reach aquatic plants.

"source control BMPs" – In general, activities or programs to educate the public or provide low cost non-physical solutions, as well as facility design or practices aimed to limit the contact between pollutant sources and stormwater or authorized non-storm water. Examples include: activity schedules, prohibitions of practices, street sweeping, facility maintenance, detection and elimination of illicit connections and illegal dumping, and other non-structural measures. Facility design examples include providing attached lids to trash containers, or roof or awning over material and trash storage areas to prevent direct contact between water and pollutants. Additional examples are provided in Section 4 of Supplement A to the DAMP dated April 1996.

State Board - California State Water Resources Control Board

"storm water" – Runoff from urban, open space, and agricultural areas consisting only of those discharges that originates from precipitation events. Storm water is that portion of precipitation that flows across a surface to the MS4 or receiving waters. Examples of this phenomenon include: the water that flows off a building's roof when it rains (runoff from an impervious surface); the water that flows into streams when snow on the ground begins to melt (runoff from a semi-pervious surface); and the water that flows from a vegetated surface when rainfall is in excess of the rate at which it can infiltrate into the underlying soil (runoff from a pervious surface). During precipitation events in urban areas, rain water picks up and transports pollutants through storm water conveyance systems, and ultimately to Waters of the U.S.

TDS - Total dissolved solids.

TMDL (Total Maximum Daily Load) – TMDL is the maximum amount of a pollutant that can be discharged into a water body from all sources (point and non-point) and still maintain water quality standards. Under CWA Section 303(d), TMDLs must be developed for all water bodies that do not meet water quality standards after application of technology-based controls.

"toxicity" – Adverse responses of organisms to chemicals or physical agents ranging from mortality to physiological responses such as impaired reproduction or growth anomalies.

TSS - Total suspended solids.

Urban Runoff – Urban Runoff includes those discharges from residential, commercial, industrial, and construction areas within the Permit Area and excludes discharges from feedlots, dairies, farms, and open space. Urban Runoff discharges consist of storm water and non-storm water surface runoff from drainage sub-areas with various, often mixed, land uses within all of the hydrologic drainage areas that discharge into the Waters of the U. S. In addition to Urban Runoff, the MS4s regulated by this Order receive flows from agricultural activities, open space, state and federal properties and other non-urban land uses not under the control of the Permittees. The quality of the discharges from the MS4s varies considerably and is affected by, among other things, past and present land use activities, basin hydrology, geography and geology, season, the frequency and duration of storm events, and the presence of past or present illegal and allowed disposal practices and illicit connections.

The Permittees lack legal jurisdiction over storm water discharges into their respective MS4s from agricultural activities, California and federal facilities, utilities and special districts, Native American tribal lands, wastewater management agencies and other point and non-point source discharges otherwise permitted by or under the jurisdiction of the Regional Board. The Regional Board recognizes that the Permittees should not be held responsible for such facilities and/or discharges. Similarly, certain activities that generate pollutants present in Urban Runoff are beyond the ability of the Permittees to eliminate. Examples of these include operation of internal combustion engines, atmospheric deposition, brake pad wear, tire wear, residues from lawful application of pesticides, nutrient runoff from agricultural activities, and leaching of naturally occurring minerals from local geography.

USEPA - United States Environmental Protection Agency

Waste Discharge Requirements – As defined in Section 13374 of the California Water Code, the term "waste discharge requirements" is the equivalent of the term "permits" as used in the Federal Water Pollution Control Act, as amended. The Regional Board usually reserves reference to the term "permit" to Waste Discharge Requirements for discharges to surface Waters of the U.S.

Water Code - California Water Code

Waters of the U.S. – Waters of the U.S. can be broadly defined as navigable surface waters and all tributary surface waters to navigable surface waters. Groundwater is not considered to be a Waters of the U.S. As defined in 40 CFR 122.2, the Waters of the U.S. are defined as: (a) All waters, which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide; (b) All interstate waters, including interstate "wetlands;" (c) All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mudflats, sandflats, "wetlands," sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds the use, degradation or destruction of which would affect or could affect interstate or foreign commerce including any such waters: (1) Which are or could be used by interstate or foreign travelers for recreational or other purposes; (2) From which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or (3) Which are used or could be used for industrial purposes by industries in interstate commerce; (d) All impoundments of waters otherwise defined as Waters of the U.S. under this definition; (e) Tributaries of waters identified in paragraphs (a) through (d) of this definition; (f) The territorial seas; and (g) "Wetlands" adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (a) through (f) of this definition. Waters of the U.S. do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for the purposes of the CWA, the final authority regarding CWA jurisdiction remains with the USEPA.

"water quality objectives" – Numerical or narrative limits on constituents or characteristics of water designated to protect designated beneficial uses of the water [California Water Code Section 13050 (h)]. California's water quality objectives are established by the State/Regional Water Boards in the Water Quality Control Plans.

As stated in the Porter-Cologne requirements for discharge (CWC 13263): "(Waste discharge) requirements shall implement any relevant water quality control plans that have been adopted, and shall take into consideration the beneficial uses to be protected, the water objectives reasonably required for that purpose, other waste discharges, the need to prevent nuisance, and the provisions of Section 13241."

Numeric or narrative limits for pollutants or characteristics of water designed to protect the beneficial uses of the water. In other words, a water quality objective is the maximum concentration of a pollutant that can exist in a Receiving Water and still generally ensure that the beneficial uses of the Receiving Water remain protected (i.e., not impaired). Since water quality objectives are designed specifically to protect the beneficial uses, when the objectives are violated the beneficial uses are, by definition, no longer protected and become impaired. This is a fundamental concept under the Porter Cologne Act. Equally fundamental is Porter Cologne's definition of pollution. A condition of pollution exists when the water quality needed to support designated beneficial uses has become unreasonably affected or impaired; in other words, when the water quality objectives have been violated. These underlying definitions (regarding beneficial use protection) are the reason why all waste discharge requirements implementing the federal NPDES regulations require compliance with water quality objectives. (Water quality objectives are also called water quality criteria in the CWA.)

"water quality standards" – are defined as the water quality goals of a waterbody (or a portion of the waterbody) designating beneficial uses (e.g., swimming, fishing, municipal drinking water supply, etc.,) to be made of the water and the water quality objectives or criteria necessary to protect those uses.

"watershed" – That geographical area which drains to a specified point on a watercourse, usually a confluence of streams or rivers (also known as drainage area, catchments, or river basin).

Stephen E. Stump
Chief of Regulatory Division
Riverside County Flood Control
And Water Conservation District

Litter Management Best Management Plan Evaluation

The Riverside County NPDES MS4 Permit Technical Advisory Committee (TAC) has assessed the relative efficiency and cost effectiveness of anthropogenic litter management best management practices (BMPs). This assessment included available BMPs and the BMPs currently implemented for the control of anthropogenic litter including street sweeping, catch basin cleaning, deployment of trash receptacles, public education, and MS4 maintenance. The Permittees also augment the litter management program through employee/contractor training, industrial/commercial activity inspections, recycling programs including bulk-item collection, participation in watershed clean-up efforts, and illegal dumping retrieval.

The BMP assessment included a review of visual observation information collected by the Permittees regarding the materials collected from the MS4 (e.g., paper, plastic, wood, glass, vegetative litter and other similar debris) and descriptions of the main sources (e.g., office, residential, commercial and industrial waste) and problem areas. Based on this assessment, recommendations are provided for improving the effectiveness of the currently implemented measures and other appropriate BMPs to control anthropogenic litter in Urban Runoff.

Visual Observation Procedures

The Permittees recorded visual observations of anthropogenic litter removed from streets, storm drain inlets and the MS4 during the 2004-2005 fiscal year. The purpose of these visual observations was to collect information regarding the types of anthropogenic litter and their relative sources. A Visual Observation Form (attached) was developed by the TAC to record field observations of sources and types of litter found in the MS4. The Visual Observation Form was used by Permittee maintenance crews to record visual observations during catch basin cleaning and channel maintenance.

Training on making the visual observations and completing the Visual Observation Form was provided to the maintenance crews by the maintenance supervisors and guidelines were also listed on the back of the form. One form was filled out per catch basin or other inlet structure when the structure was maintained and when anthropogenic sources of litter were collected from the system. The amount of each type of litter was calculated based on visual estimates of the total weight of the litter and the estimated percentage of each type of litter present. The total percentage of litter had to equal 100%. The surrounding land use observed in the field was also checked on the form to correlate the type of litter with the surrounding land use. Visual observation data is provided in the Permittee Annual Report submittals.

Review of Results of Visual Observations

Materials Collected from the MS4 and Sources of Litter

The majority of litter appears to originate from residential sources, with the remaining attributed to commercial activities. Litter associated with residential activities included common household waste including newspapers, cardboard, cans, glass, plastic bottles and landscaping wastes. Larger items collected consisted of building lumber, discarded propane tanks, signs and wooden

posts, children's toys, furniture, and household appliances. Another noteworthy finding was the presence of larger quantities of litter in catch basins located near freeway interchanges and along commercial corridors.

Preliminary findings of the visual observations indicate that on a weight basis, paper was the most prevalent type of litter. Paper was found to be distributed equally in residential and commercial areas and slightly less in industrial areas. The second most prevalent litter type was plastic. Plastic litter was found to be distributed equally amongst residential, commercial and industrial sources. Vegetative litter was not found in industrial areas, however wood and other types of litter (such as cement, plaster, Styrofoam, and brick) were found to be predominant in industrial areas.

BMP Evaluation

The Permittees intend to utilize the information collected in this study to identify areas where street sweeping or catch basin cleaning may need to be intensified. Some conclusions can also be drawn based on the type of pollutants found (or not found) in land uses, which can be useful in developing targeted BMP programs. Street sweeping is performed on a regular basis and has been found to be adequate. Maintenance departments also include newly developed areas in sweeping and catch basin cleaning. Sweeping is typically increased as needed to address specific problem areas, seasonal (leaf season) or storm event considerations, or special public events.

Recommendations for Improving the Effectiveness of Litter Management based on Survey Results

Based on the litter assessment, the TAC has determined that anthropogenic litter is not evenly distributed throughout the Permit area. To more effectively manage litter, the priority for implementation of litter BMPs should be in those locations with heaviest and most frequent litter accumulations. These areas vary and are known by Permittee maintenance staff. Examples of recommended improvements to litter management include the following:

- streets are swept at higher frequencies in those areas that have higher accumulations of litter,
- catch basins that are known to accumulate more litter are cleaned on a more frequent basis,
- portions of the MS4 that accumulate more litter are cleaned more frequently, and
- consideration of parking controls or sweeping notices in residential areas where vehicles parked along the street prevent the sweeper from clearing trash and debris.

This document is one chapter from the EPA "Handbook for Developing Watershed Plans to Restore and Protect Our Waters," published in March 2008. The reference number is EPA 841-B-08-002. You can find the entire document http://www.epa.gov/owow/nps/watershed_handbook.

Handbook for Developing Watershed Plans to Restore and Protect Our Waters

Chapter 7. Analyze Data to Characterize the Watershed and Pollutant Sources

March 2008

Handbook Road Map

- 1 Introduction
- 2 Overview of Watershed Planning Process
- 3 Build Partnerships
- 4 Define Scope of Watershed Planning Effort
- 5 Gather Existing Data and Create an Inventory
- 6 Identify Data Gaps and Collect Additional Data If Needed
- 7 Analyze Data to Characterize the Watershed and Pollutant Sources
- 8 Estimate Pollutant Loads
- 9 Set Goals and Identify Load Reductions
- 10 Identify Possible Management Strategies
- 11 Evaluate Options and Select Final Management Strategies
- 12 Design Implementation Program and Assemble Watershed Plan
- 13 Implement Watershed Plan and Measure Progress

7. Analyze Data to Characterize the Watershed and Pollutant Sources

Chapter Highlights

- Identifying locations of impairments and problems
- Determining timing of impairments and problems
- Identifying potential sources
- Determining areas for quantifying source loads

Read this chapter if...

- You want to satisfy element a of the section 319 guidelines—identification of causes and sources that need to be controlled
- You want to characterize the general environmental conditions in your watershed
- You're not sure what types of data analyses you should use
- You want to conduct a visual assessment as part of your data analysis
- You want to link your analysis results with the causes and sources of pollutants in the watershed
- You want to identify critical areas in the watershed that will need management measures to achieve watershed goals

7.1 Analyze Data to Identify Pollutant Sources

Chapter 5 discussed the first step of the watershed characterization process—identifying and gathering available data and information to assess the watershed and create a data inventory. Chapter 6 discussed the next step—conducting a preliminary data review, identifying any data gaps, and then collecting additional data if needed. All of this information will now be used in the next step—data analysis to characterize the watershed. This analysis supports the identification of watershed pollutant sources and causes of impairment, which is essential to defining watershed management needs. This chapter highlights the types of data analyses commonly used to characterize water quality and waterbody conditions and to identify watershed sources contributing to impairments and problems.

⑨ This phase of the watershed planning process should result in the first of the nine elements that EPA requires in a section 319-funded watershed plan. Element *a* is “*Identification of causes and sources or groups of similar sources that need to be controlled to achieve load reductions, and any other goals identified in the watershed plan.*”

Remember that data gathering and analysis is an ongoing, iterative process. Data examined in this phase will continue to be used in subsequent activities, such as identifying and evaluating management measures and tracking implementation efforts.

7.1.1 Focus Your Analysis Efforts

© Although many techniques are described in this chapter, you will likely choose only a selected combination of the techniques in your watershed. The process of conducting data analyses to characterize your watershed and its pollutant sources begins with broad assessments such as evaluating the averages, minimums, and maximums of measured parameters at all watershed stations. The analyses are then systematically narrowed, with each step building on the results of the previous analysis. Through careful analysis you’ll obtain a better understanding of the major pollutant sources, the behavior of the sources, and their impacts on the waterbodies. An understanding of the watershed conditions and sources is also the basis for determining the appropriate method for quantifying the pollutant loads.

In addition, the kinds of data analyses you perform will be determined by the amount of available data. For example, if you have data for several stations in a watershed, you’ll be able to evaluate geographic variations in water quality throughout the watershed—an analysis you could not do with data for only one station.

Table 7-1 provides examples of data analysis activities and the tools used in various steps of the watershed planning process. It gives you an idea of how the parameter or analytical techniques might vary depending on where you are in the process and your reasons for analysis.

7.1.2 Use a Combination of Analysis Types

Because data analysis techniques are used to support a variety of goals and involve multiple types of data, a combination of techniques is usually used. Less-detailed analyses, such as evaluating summary statistics, might be conducted for certain pollutants, whereas more detailed analyses might be conducted for others, depending on the goals of the plan and the pollutants of concern. Data analysis is typically an iterative process that is adapted as results are interpreted and additional information is gathered.

Table 7-1. Examples of the Types of Data-related Activities Conducted throughout the Watershed Planning Process

Watershed Planning Step	Type of Data	Goal of Data Analysis	Example Activity
Characterize Watershed	<ul style="list-style-type: none"> Previously conducted studies (e.g., TMDLs, 305(b) report, USGS water quality reports, university studies) 	Generally characterize the watershed and identify the most important problems for further analysis.	<ul style="list-style-type: none"> Review available reports and assessments.
	<ul style="list-style-type: none"> Watershed data (e.g., land use, soils, habitat) Chemical instream data Biological instream data Physical data Habitat data 	Perform targeted analysis of available data to characterize the waterbody and watershed. Examples: <ul style="list-style-type: none"> Identify sources Characterize the impairment Evaluate spatial trends Evaluate temporal trends Identify data gaps 	<ul style="list-style-type: none"> Compare data to water quality standards to identify timing and magnitude of impairment. Review monthly statistics to identify seasonal variations. Use GIS at watershed stations to identify spatial variations in water quality and potential sources of pollutants.
Set Goals and Identify Solutions	<ul style="list-style-type: none"> Watershed data (e.g., land use, soils, population, habitat) Chemical instream data Biological instream data Physical data Meteorological data Habitat data 	Appropriately represent watershed and waterbody in the model for the most accurate simulation of watershed loads.	<ul style="list-style-type: none"> Use data to establish a non-modeling analysis (e.g., use observed data to establish a spreadsheet mass balance calculation). Use data for model setup (e.g., identify appropriate model parameter values, establish watershed characteristics such as land use and soils). Compare observed data to model output for calibration and validation.
Implement and Evaluate	Instream monitoring data for the parameters of concern (e.g., nutrients)	Evaluate the effectiveness of management measures and track the progress of water quality improvement.	<ul style="list-style-type: none"> Compare data collected upstream and downstream of management practices. Compare data collected before and after implementation of management practices to track water quality improvement.

Note: TMDL = Total Maximum Daily Load; USGS = U.S. Geological Survey; GIS = geographic information system.

7.1.3 Consider Geographic Variations

The kinds of analyses and the level of detail used in your data analysis will vary within the watershed depending on the pollutants of concern. For example, if bacteria loading from livestock operations is a primary concern in the watershed, detailed land use analysis might be necessary to identify pasturelands and evaluate proximity to streams and water access for livestock, as well as to identify and characterize areas of cropland that receive manure applications. In addition, detailed water quality analyses might be needed for the areas that contain livestock to evaluate the timing and magnitude of impacts as related to livestock grazing schedules and access to waterbodies. For other areas of the watershed, general water quality characterization will be sufficient, and low-level evaluations of stream characteristics, watershed soils, and other types of data will be acceptable given the focus of the data analysis.

7.1.4 Incorporate Stakeholders' Concerns and Observations

Stakeholder concerns and goals will also help to determine what kinds of analyses are needed. If the stakeholders and the earlier characterization identified bacteria- and metals-associated impacts from developed areas as a primary concern, the data analysis will focus on characterizing those parameters and the locations, types, or timing of pollutant loading from urban and residential sources in the watershed. If a specific source is expected to be contributing to water quality problems, more detailed analyses might be conducted on data collected upstream and downstream of that source, or smaller time scales (e.g., daily concentrations) might be evaluated. Data analysis in the remainder of the watershed would be more coarse, identifying simple summary statistics (e.g., monthly minimum, maximum, average) sufficient for general characterization of identified subwatersheds. Table 7-2 illustrates this concept with examples of different levels of effort for the various types of data used in watershed characterization. Other factors to consider regarding level of detail include relative costs of remediation, risks to human health and aquatic life, and level of disagreement among stakeholders—all of which would likely increase the level of detail needed.

Table 7-2. Examples of the Level of Detail and Effort for Typical Types of Data

Type of Data	Increasing level of complexity		
	Low	Moderate	High
Instream (e.g., water quality, flow)	Summary statistics (e.g., minimum, average, maximum) for watershed stations	Spatial analysis of water quality using instream water quality data and GIS coverages	Spatial and temporal analysis of multiple instream parameters and GIS mapping data (often combined with modeling and supplemental monitoring)
Land use	General distribution of land use types throughout the watershed, using broad categories (e.g., agriculture, urban)	Specific identification of land use areas by subwatershed, including more detailed categories (e.g., cropland, pasture, residential, commercial)	Statistical analysis of land use areas in relation to water quality conditions (e.g., regression analysis between amount of impervious area and average flow or water quality)
Soils	General distribution of soil types based on available information	GIS analysis of the locations and types of soil series	Detailed analysis of soil distribution, including identification of proximity to streams, erosion potential, and other soil characteristics affecting soil erosion and transport
Habitat	General distribution of habitats based on available data	Mapping of critical habitats and their buffers	Landscape pattern measurement near critical habitat areas with GIS modeling

Once the focus of the data analysis has been identified, the relevant data are compiled and analyses are conducted. The following sections discuss the typical types of data analyses used to support watershed characterization and the primary data analysis techniques available to evaluate the watershed and identify causes and sources.

7.2 Analyze Instream and Watershed Data

Data analysis helps to evaluate spatial, temporal, and other identifiable trends and relationships in water quality. Analysis of instream data is needed to identify the location, timing, or behavior of potential watershed sources and their effect on watershed functions such as

hydrology, water quality, and aquatic habitat. Analysis of habitat data is needed to identify areas that need to be restored or protected. You developed a preliminary assessment of the watershed during the first and second phases of watershed characterization. Now, with a more comprehensive dataset, you can perform a more detailed and definitive analysis.

One way to organize and focus the data analysis is to consider the specific watershed characteristics and the questions that need to be answered before an appropriate management strategy can be developed. Use  Worksheet 7-1 to help determine the types of analyses you might need to conduct for water quality. Use  Worksheet 7-2 to help determine the types of analyses you might need to conduct for habitat assessment and protection.  Blank copies are provided in appendix B.

 **Worksheet 7-1** *What Data Analysis Do We Need to Conduct for Water Quality?*

Questions to help determine what kinds of data analyses are needed

Question	Section to refer to for assistance
1. Are water quality standards being met? If so, are they maintaining existing levels?	7.2.1 (Confirm Impairments) 7.2.2 (Summary Statistics)
2. Is water quality threatened?	7.2.1 (Confirm Impairments) 7.2.2 (Summary Statistics)
3. Is water quality impaired?	7.2.1 (Confirm Impairments) 7.2.2 (Summary Statistics)
4. Are there known or expected sources causing impairment?	7.2.7 (Visual Assessment)
5. Where do impairments occur?	7.2.3 (Spatial Analysis)
6. When do the impairments occur? Are they affected by seasonal variations?	7.2.4 (Temporal Analysis)
7. Under what conditions (e.g., flow, weather) are the impairments observed?	7.2.4 (Temporal Analysis) 7.2.5 (Other Trends and Patterns)
8. Do multiple impairments (e.g., nutrients and bacteria) coexist?	7.2.5 (Other Trends and Patterns)
9. Are there other impairments that are not measured by water quality standards?	7.2.6 (Stressor Identification)

Questions to answer based on the results of the data analysis:

1. What beneficial uses for the waterbodies are being impaired? What pollutants are impairing them?
2. What are the potential sources, nonpoint and point, that contribute to the impairment?
3. When do sources contribute pollutant loads?
4. How do pollutants enter the waterbody (e.g., runoff, point sources, contaminated ground water, land uses, ineffective point source treatment, pipe failures)?
5. What characteristics of the waterbody, the watershed, or both could be affecting the impairment (e.g., current or future growth, increased industrial areas, future NPDES permits, seasonal use of septic systems)?
6. Revisit the conceptual model showing the watershed processes and sources, and revise it if necessary

 **Worksheet 7-2** *What Data Analysis Do We Need to Conduct for Habitat Assessment and Protection?*

1. Where are critical habitats (e.g., headwaters, wetlands, forests, springs and seeps) and their buffers located?
2. What is their conservation status?
3. What is their condition?
4. Are they threatened?
5. Are there opportunities to protect or restore buffers or fill a habitat connectivity gap to reduce fragmentation and protect source water?
6. How does spatial hierarchy (e.g., site, subwatershed, watershed, basin, and region) factor into habitat protection and restoration goals?
7. What are the current and future development projections and how will they affect habitats and their buffers?

Typical analyses used to address these questions include statistical analysis, spatial analysis, temporal analysis, trends and relationships, and flow and load duration curves. It's important to note that most of the analyses discussed in this section focus on water quality monitoring data because many watershed goals can be directly or indirectly linked to instream water quality conditions. In addition, water quality is an indicator of the general watershed conditions and pollutant source types, locations, and behavior. However, you should also broaden the evaluation of watershed conditions by incorporating additional data types (e.g., land use, weather, and stream morphology) discussed in chapter 5, as necessary or appropriate for your watershed. Further, to meet watershed conservation, protection, and restoration goals and management measures, you should analyze habitat data and use assessment tools to identify priority habitats and their buffers, their configuration in a watershed, and the key habitat conditions and habitat-forming processes. A summary of the various types of analyses used in a watershed characterization is provided below.

7.2.1 Confirm Impairments and Identify Problems

The first step in characterizing your watershed involves understanding the water quality impairments and designated use impacts occurring in the watershed. The following reports and databases are available to support this activity:

- **305(b) report (as part of the Integrated Report)**—summarizes designated use support status for waters in the state
- **303(d) lists (as part of the Integrated Report)**—identify waters not meeting water quality standards
- **EPA's Assessment Database (ADB)**—includes data used in 305(b) and 303(d) assessments
- **TMDL Tracking System (stand-alone or through WATERS)**—includes locations of 303(d)-listed waterbodies and provides downloadable geographic information system (GIS) coverages

Although these references provide the necessary information to *identify* the types of water quality problems occurring in your watershed, it's likely that you'll have to analyze the

available monitoring data yourself to fully *characterize and understand* the problems. This analysis typically involves comparing available monitoring data to water quality standards, but in a way that goes beyond the assessment already completed by the state for section 303(d) and 305(b) assessments. When identifying impaired waterbodies for the 303(d) list, states usually compare available monitoring data to applicable water quality criteria and, on the basis of their listing guidelines and criteria (e.g., percentage of samples above the criteria), determine which waters don't meet the criteria. In evaluating impairments in your watershed, you don't want to simply duplicate the state's efforts. ☹ Instead, use the 305(b) and 303(d) information to target your analyses—to identify which waterbodies are impaired or threatened—and begin your analysis there. (You should also include in your analysis those waterbodies identified by stakeholders as degraded but not included in the state assessments.)

EPA's Assessment Database

EPA's new Assessment Database (ADB) application provides a framework for managing water quality assessment data. The ADB is designed to serve the needs of states, tribes, and other water quality reporting agencies for a range of water quality programs (e.g., CWA sections 305(b), 303(d), and 314). The ADB stores assessment results related to water quality standards designated use attainment, the pollution associated with use impairments, and documentation of probable pollution sources. The ADB can be used to generate several pre-formatted reports, as well as conventional data tables and lists. ☹ For more information on using the ADB, go to www.epa.gov/waters/adb. The most recent EPA Integrated Report guidance includes an increased emphasis on using the ADB to meet reporting requirements.

It's a good idea to do a general analysis (e.g., summary statistics) of all the waterbodies and associated data in your watershed, but you can focus the more in-depth evaluation of impairment on those waterbodies known to have problems. To better understand the watershed impairments, you can analyze the water quality and instream data in a variety of ways. The first likely analysis is simply the magnitude of the impairment—how bad is the problem? Identifying the percentage of samples that violate standards provides insight into the level of impairment in the watershed, or at a particular location. Using a graphical display of water quality data compared to applicable criteria is also an easy way to generally illustrate the frequency and magnitude of standards violations, as shown in figure 7-1. A temporal analysis of water quality versus standards can be used to identify the times of year, season, month, and even day when the impairment is occurring or is the worst. Temporal and other analyses are discussed further in this section. These analyses are used to understand the general watershed conditions and to support identification of pollutant sources, but they also provide information specific to the distribution, timing, and magnitude of water quality impairment.

7.2.2 Summary Statistics

Statistical analyses are essential tools for describing environmental data and evaluating relationships among different types of data. You might not need to conduct in-depth statistical testing to characterize your watershed, but it's often useful to develop summary statistics to summarize your available datasets, to help in preliminary analysis, and to communicate your results to stakeholders and the public. Summary statistics include such characteristics as range (e.g., minimum, maxi-

Figure 7-1. Example Graph of Observed Aluminum Concentrations Compared to Water Quality Criteria

More on Statistics

This section discusses the typical types of data analyses used to support watershed characterization and identification of pollutant sources. Each analysis can be conducted with varying degrees of detail and complexity. In addition, it might be useful to perform more detailed statistical tests. For example, a Mann-Kendall test can be applied to long-term datasets to indicate whether there is a statistically significant increasing or decreasing trend in the water quality data. Available references with information on statistical analysis of environmental data include

Helsel, D.R., and R.M. Hirsch. 2002. Statistical Methods in Water Resources. Chapter A3 in Book 4, Hydrologic Analysis and Interpretation, of Techniques of Water-Resources Investigations of the United States Geological Survey.

↳ <http://water.usgs.gov/pubs/twri/twri4a3>.

NRCS (Natural Resources Conservation Service). 1997. *National Handbook of Water Quality Monitoring*. 450-vi-NHWQM. National Water and Climate Center, Portland, Oregon.

mum), central tendency (e.g., mean, median), and variability (standard deviation, coefficient of variation). Figure 7-2 defines many of the commonly used statistical terms. Summary statistics should be computed for all stations and relevant data (e.g., pollutants of concern) as one of the first steps in your data analysis. Microsoft Excel and other spreadsheet programs make developing summary statistics simple. The program can automatically calculate any of the statistical functions based on the dataset. In addition, you can create Pivot tables in Excel that calculate several statistical functions for any combination of the data at once (e.g., by pollutant by station). It is useful to also calculate the number or percentage of samples violating water quality criteria to include in your summary statistics for each station.

Measures of Range: Identify the span of the data from low to high.

Minimum: The lowest data value recorded during the period of record.

Maximum: The highest data value recorded during the period of record.

Measures of Central Tendency: Identify the general center of a dataset.

Mean: The sum of all data values divided by the sample size (number of samples). Strongly influenced by outlier samples (i.e., samples of extreme highs or lows); one outlier sample can shift the mean significantly higher or lower.

Median ($P_{0.50}$): The 50th percentile data point; the central value of the dataset when ranked in order of magnitude. The median is more resistant to outliers than the mean and is only minimally affected by individual observations.

Measures of Spread: Measure the variability of the dataset.

Sample variance (s^2) and its square root, standard deviation (s): The most common measures of the spread (dispersion) of a set of data. These statistics are computed using the squares of the difference between each data value and the mean, and therefore outliers influence their magnitudes dramatically. In datasets with major outliers, the variance and standard deviation might suggest much greater spread than exists for most of the data.

Interquartile range (IQR): The difference between the 25th and 75th percentile of the data. Because the IQR measures the range of the central 50 percent of the data and is not influenced by the 25 percent on either end, it is less sensitive to extremes or outliers than the sample variance and standard deviation.

Measures of Skewness: Measures whether a dataset is asymmetric around the mean or median and suggests how far the distribution of the data differs from a normal distribution.

Coefficient of skewness (g): Most commonly used measure of skewness. Influenced by the presence of outliers because it is calculated using the mean and standard deviation.

Quartile skew coefficient (qs): Measures the difference in distances of the upper and lower quartiles (upper and lower 25 percent of data) from the median. More resistant to outliers because, like the IQR, uses the central 50 percent of the data.

Figure 7-2. Commonly Used Summary Statistics

7.2.3 Spatial Analysis

If evaluation of the summary statistics for the water quality stations in your watershed indicates noticeable differences in water quality throughout the watershed, you should do a more focused analysis of spatial variation in water quality and other waterbody monitoring data.

Spatial analysis of available waterbody data can be useful to

- Determine the general distribution of water quality or habitat conditions
- Identify the locations of areas of concern or potential major sources
- Determine the impact of a specific source
- Identify the effect of a management practice or control effort

The spatial distribution of water quality conditions in the watershed might indicate the location of “hot spots” and sources potentially affecting impairment. Spatial analysis of data is also useful in evaluating the potential impacts of specific sources, when sufficient data are available. Evaluating the difference in paired observations from stations upstream and downstream of a potential source can indicate the impact of the source on instream conditions. Similar data analysis can be conducted on data available upstream and downstream of a management practice to evaluate the effectiveness of the management practice in reducing pollutant loads to the waterbody.

Simply reviewing a table of summary statistics for each station in the watershed can identify areas of varying water quality. When dealing with a large watershed with multiple stations, however, a GIS can be used to effectively present and evaluate spatial variations in water quality conditions, as shown in the example map in figure 7-3. Presenting water quality summaries by station throughout a watershed in GIS also allows for identification of corresponding watershed conditions or sources that might be causing the spatial variations, such as land use distribution and location of point sources. This information is important for identifying the potential sources that might be causing the watershed problems and impairments.

Even if sufficient monitoring data are not available to adequately evaluate spatial variation in water quality, you should still evaluate other available watershed data to understand the spatial distribution of characteristics that are likely influencing waterbody conditions, such as land use, soils, and location of permitted sources. GIS is a very useful tool for displaying and evaluating these kinds of data.

7.2.4 Temporal Analysis

Another important analysis is the evaluation of temporal trends in water quality conditions. Evaluating temporal patterns can assist in identifying potential sources in the watershed, seasonal variations, and declining or improving water quality trends. Temporal analyses can include long-term trend analysis to identify generally increasing or decreasing trends in data and more focused analysis of monthly, seasonal, and even daily and hourly variations.

Figure 7-3. Example Map of Average Total Dissolved Solids Concentration Throughout a Watershed

Figure 7-4. Example Graph of Monthly Statistics for Fecal Coliform Bacteria

Degraded water quality during certain months or seasons can indicate the occurrence of a source that is active only during those times. For example, elevated concentrations of nutrients or bacteria during the summer months (figure 7-4) might indicate increased source activity, such as livestock grazing, during those months. It might also indicate a need for further analysis of other watershed conditions (e.g., weather, flow) that can exacerbate the impairment during the summer months. For example, warmer temperatures during the summer might increase the productivity of algae, leading to greater decreases in dissolved oxygen.

7.2.5 Other Trends or Patterns

It is often beneficial to evaluate relationships and trends in the available data other than spatial and temporal trends. Important examples include

- Evaluating the relationship between flow and instream water quality (see chapter 5 for data sources)
- Documenting the relationship between related pollutants
- Evaluating the relationship of instream conditions to other watershed factors (e.g., land use, source activity)

Flow Versus Water Quality

An identifiable relationship between flow and instream water quality concentrations can indicate what types of pollutant sources dominate the instream impairment and can help to identify critical conditions surrounding the impairment. For example, runoff-driven non-point sources typically dominate instream water quality conditions during periods of high flow resulting from rainfall/runoff events, whereas point sources that provide relatively constant discharges to receiving waters usually dominate water quality during low flow, when there is less water to dilute effluent inputs.

Using Duration Curves to Connect the Pieces

America's Clean Water Foundation published an article discussing duration curves and their use in developing TMDLs (Cleland 2002). The duration curves act as an indicator of relevant watershed processes affecting impairment, important contributing areas, and key delivery mechanisms. To read the full article and get more information on the use of duration curves to diagnose seasonal impacts and potential sources, go to www.tmdl.net/tipstools/docs/BottomUp.pdf.

There are several options for evaluating the relationship between flow and a water quality parameter, including visually evaluating time series data, developing a regression plot, calculating flow-weighted averages, evaluating monthly averages, and developing a flow duration curve.

A flow duration curve can be a useful diagnostic tool for evaluating critical conditions for watershed problems and the types of sources that could be influencing waterbody conditions. Flow duration curves graph flows based on their occurrence over the period of record. Flows are ordered according to magnitude, and then a percent frequency is assigned to each, representing the percentage of flows that are less than that flow. For example, a flow percentile of zero corresponds to the lowest flow, which exceeds none of the flows in that

record. The percentage of 100 corresponds to the highest flow, which exceeds all the flows in that record. The flow duration is often plotted with corresponding pollutant concentrations to evaluate the relationship between water quality and flow. To do this, you should isolate matching flow and water quality and plot the flow and concentration data as a function of flow percentile.

A variation of the flow duration curve is the load duration curve, which plots observed pollutant loads as a function of flow percentile. Matching water quality and flow (measured on the same day) are used to calculate observed loads, by multiplying flow by pollutant concentration and an appropriate conversion factor. The loads are then plotted along with the flow in order of flow percentile. The load duration curve provides information on when loading occurs.

As shown in the example load duration curve (figure 7-5), the total dissolved solids (TDS) concentrations tend to follow a pattern similar to the flow, with lower concentrations occurring during lower flows and elevated concentrations during higher flows. This indicates that surface runoff (nonpoint source runoff or stormwater discharges) is likely the source of elevated TDS rather than point source discharges. The flow duration method does not allow you to identify specific sources (e.g., residential versus agricultural), but it provides useful information on the conditions under which problems occur and the general types of sources affecting the waterbody.

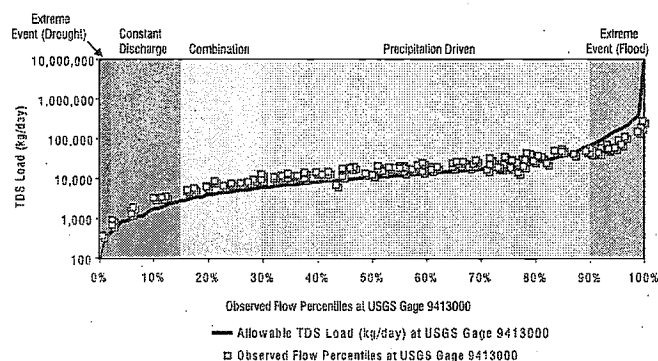

Figure 7-5. Example Load Duration Curve

Relationships between Pollutants

It's also important to evaluate the correlation of instream concentrations (and loading) of pollutants of concern to other parameters that represent the same impairment or are likely being contributed by similar sources. For example, metals often attach to sediments, resulting in increased metals loading during times of high sediment erosion and runoff. Establishing a correlation between instream sediment and metal concentrations can indicate that metals loading in the watershed is sediment-related. Understanding these relationships will be important when establishing load reductions and selecting appropriate management activities.

Using the Correlation of Phosphorus, pH, and Chlorophyll a to Understand Instream Conditions and Focus Management Efforts

The Vandalia Lake, Illinois, TMDL establishes load reduction goals for total phosphorus to address impairments from both phosphorus and pH. Fluctuations in pH can be correlated to photosynthesis from algae. Chlorophyll a indicates the presence of excessive algal or aquatic plant growth, which is a typical response to excess phosphorus loading. Reducing total phosphorus is expected to reduce algal growth, thus resulting in attainment of the pH standard. Available monitoring data for the lake were used to evaluate the relationship between pH, chlorophyll a, and total phosphorus. The general relationships suggested that controlling total phosphorus will decrease chlorophyll a concentrations, which will in turn reduce pH into the range required for compliance with water quality standards. For more information, go to www.epa.state.il.us/water/tmdl/report/vandalia/vandalia.pdf.

Waterbody Conditions Versus Watershed Characteristics

Evaluating relationships between instream conditions and watershed features or conditions will also facilitate identifying sources and establishing successful management goals and focused implementation efforts. For example, performing statistical analyses on instream data and watershed features, such as weather patterns, land use (e.g., percent impervious, area of urban), or soils (e.g., erodibility), can establish a quantitative link between watershed conditions and the resulting instream conditions. It might also be appropriate to divide data into separate datasets representing certain time periods or conditions for evaluation (e.g., storm event versus base flow, irrigation season, grazing season).

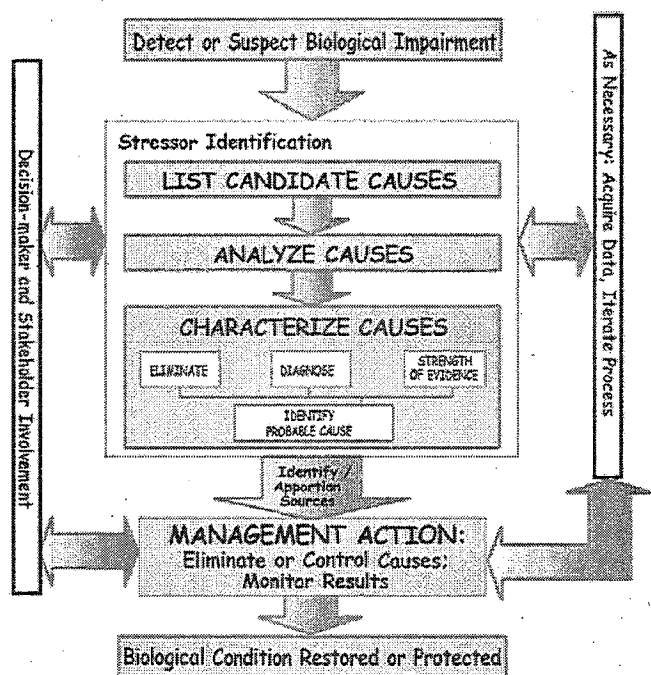

Figure 7-6. Stressor Identification Process

7.2.6 Stressor Identification

When waterbodies experience biological impairment due to unknown causes, stressor identification is used to identify the most likely causes of the impairment (figure 7-6). This formal method of causal evaluation can be used in a number of ways:

- To increase confidence that costly remedial or restoration efforts are targeted at factors that can truly improve biological condition
- To identify causal relationships that are otherwise not immediately apparent
- To prevent biases or lapses of logic that might not be apparent until a formal method is applied

↳ For a detailed description of the stressor identification process, see EPA's *Stressor Identification Guidance Document* (USEPA 2000b; www.epa.gov/waterscience/biocriteria/stressors/stressorid.html). In addition, two stressor identification modules originally developed as part of EPA's 2003 National Biocriteria Workshop are available online. ↳ The SI 101 course contains several presentations on the principles of the stressor identification process: www.epa.gov/waterscience/biocriteria/modules/#si101.

EPA recently released the Causal Analysis/Diagnosis Decision Information System (CADDIS) to support determination of causes of biological impairment. CADDIS is an online tool that helps investigators in the regions, states, and tribes to find, access, organize, use, and share information to produce causal evaluations of aquatic systems. It is based on the EPA's stressor identification process. Current features of CADDIS include

- Step-by-step guide to conducting a causal analysis
- Downloadable worksheets and examples
- Library of conceptual models
- Links to helpful information

Go to the CADDIS Web site at <http://cfpub.epa.gov/caddis/home.cfm> to access CADDIS and obtain more information.

Ecological Risk Assessment

EPA has developed a wide range of tools that consider place-based, multimedia approaches to environmental management. Watershed ecological risk assessments provide resource managers with predictions of what ecological changes will occur from the stressors associated with existing conditions and alternative management decisions. For more information, go to www.epa.gov/waterscience/biocriteria/watershed/waterrisk.html.

7.2.7 Visual Assessments and Local Knowledge

It's important to remember that monitoring and GIS data can provide only a representation of your watershed. Depending on the frequency of monitoring, the data might not reflect chronic conditions but rather provide a snapshot of conditions unique to the time of sampling, especially when dealing with parameters that are highly variable and sensitive to localized impacts (e.g., bacteria counts). To make the most of your data analysis, it's important to analyze the data with an understanding of the real world. Use the data analysis to support what you already know about the watershed from the people that live and work there.

As discussed in sections 4.3.2 and 6.5.1, visual assessments (e.g., streamwalks, windshield surveys) are useful for identifying and connecting potential sources of impairment and watershed conditions and should be used to guide and support data analysis for identifying watershed sources. In watersheds with limited monitoring data, visual assessments are especially important, providing the basis for source identification.

Not only are visual assessments useful for identifying potential pollutant sources and areas on which to focus your data analysis, but they can also answer questions raised by your data analysis. For example, if your data analysis shows a dramatic decrease in water quality in a portion of your watershed, but the land use and other watershed coverages don't indicate any major sources in that area, it's a good idea to walk the stream or drive through the area to identify any possible reasons for the change. For example, your data might indicate sharp increases in sediment measures (e.g., turbidity, total suspended solids) between two monitoring stations. However, reviewing the land use maps does not suggest any activities that would account for such a dramatic increase. When you drive through the watershed, you might find a source that you would never know about without surveying the area, such as a severely eroding streambank or livestock or wildlife watering in the stream and causing resuspension of streambed sediments.

Examples of Sources You Might Miss without a Watershed Tour

- Streambank erosion
- Pipe outfalls
- Livestock (near or with access to streams)
- Wildlife (e.g., waterfowl populations on lakes and open streams)

In addition to visual inspection of the watershed, local knowledge and anecdotal information from stakeholders are often very important to successfully analyzing and interpreting your watershed data. They, too, can provide useful insight to support or guide data analysis, especially if they provide historical information that would not be identified through a present-day visual assessment. A data analysis conducted for Lake Creek, Idaho, provides an example of stakeholder anecdotal information's being crucial to identifying a watershed source. The data analysis indicated an unexplained increase in turbidity and sediment between two stations in the stream (figure 7-7). Discussing the data analyses with

stakeholders allowed TMDL developers to understand that the increase was the result of localized logging that had occurred near the stream several years earlier. Knowing that the logging had occurred explained why the turbidity levels had dramatically and quickly increased at the downstream station and were now still recovering. Without this knowledge, the TMDL might have inappropriately targeted areas that were not affecting the stream.

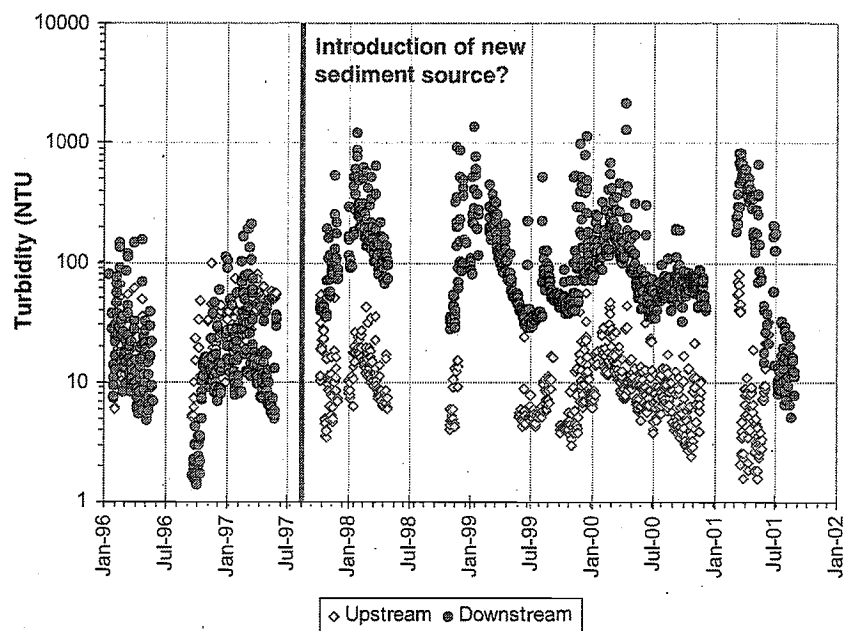

Figure 7-7. Long-term Turbidity Levels at Two Stations in Lake Creek, Idaho

7.3 Evaluate Data Analysis Results to Identify Causes and Sources

Together with the input from stakeholders and your local knowledge of the watershed, analyzing your data should lead you to an understanding of where and when problems occur in your watershed and what could be causing the problems. Ideally the data analysis phase will progress in such a manner that each analysis leads to greater understanding of the problems, causes, and sources. Suppose, for example, that you started your analysis with a calculation of summary statistics for bacteria at all the stations in your watershed. In doing so, you noticed that stations in the upstream portion of the watershed had higher averages, maximums, and minimums than the rest of the watershed. Focusing on those stations, you began to evaluate temporal variations, noting that bacteria levels were consistently higher during the spring and summer. From there you began to look at other factors that might change seasonally, including weather, flow, and surrounding land activities. You discovered that although rainfall and flow are higher during the spring, possibly delivering higher bacteria loads, they are lower during the summer. Also, rainfall and flow are higher throughout the watershed, not in only this “problem area.” So, what else might be causing the higher levels during those two seasons? By evaluating land use data for the surrounding area, you realize there are some concentrated pockets of agricultural land in the area. After talking to stakeholders and driving the watershed, you identify several acres of pastureland used for horse and cattle grazing

Watershed Assessment of River Stability and Sediment Supply

EPA provided support for the development of a three-phase technical framework of methods for assessing suspended and bedload sediment in rivers and streams. The *Watershed Assessment of River Stability and Sediment Supply* (WARSSS) tool focuses on natural variability in sediment dynamics, geologic versus anthropogenic sediment sources, erosional and depositional processes, prediction of sediment loads, streamflow changes, and stream-channel stability and departure from reference conditions. WARSSS was developed by Dr. David L. Rosgen to help watershed managers analyze known or suspected sediment problems, develop sediment remediation and management components of watershed plans, and develop sediment TMDLs, and for other uses. This Web-based assessment tool was designed for scientists that need to assess sediment-impaired waters in planning for their restoration. For more information, go to www.epa.gov/warsss/.

during the spring and summer. Much of the pastureland is in close proximity to the streams with elevated observed bacteria, and in some of the pastures animals have direct access to the streams. Such a combination of focused data analyses, visual assessments, and local knowledge is critical to identifying and understanding watershed sources.

In addition, the data analysis will identify on which sources you'll need to focus during the loading analysis discussed in chapter 8. Some sources will be expected to have a greater impact on watershed problems than others and might require more detailed analysis. For example, if runoff from developed areas is expected to be the primary cause of elevated metals in watershed streams, it might not be necessary to evaluate subcategories of agricultural or other undeveloped lands in the loading analysis. You can likely group those land uses or sources and focus on the developed areas, possibly even breaking them into more detailed categories (e.g., suburban, commercial).

7.3.1 Grouping Sources for Further Assessment

Once you understand the potential causes and sources of the watershed problems, you should decide at what level you want to characterize those sources. The next step of the process is to quantify the watershed sources—to estimate the pollutant loads contributed by the sources (chapter 8). Therefore, you should identify the sources you want to quantify. The level of detail in estimating the source loads can vary widely and will depend largely on the results of your data analysis. The analysis should give you an understanding of the sources that are affecting watershed and waterbody conditions, providing a guide for which sources need to be controlled. Therefore, it's important to identify sources at a level that will result in effective control and improvement. For example, if you have identified specific pastures in one portion of the watershed as dominating the bacteria levels in your watershed during the summer, it would not be appropriate to quantify agricultural or even pastureland sources as an annual gross load for the *entire* watershed.

Example Categories for Grouping Pollutant Sources

- Source type (e.g., nonpoint, point)
- Location (e.g., subwatershed)
- Land use type
- Source behavior (e.g., direct discharge, runoff, seasonal activities)

To facilitate estimation of source loads, and later source control, sources should be grouped into logical categories that help to prioritize and address certain pollutants, sources, or locations for more efficient and effective management. Consider the following factors and methods when grouping sources for assessment. You can combine many of the methods to create various groupings and layers of sources, relevant to the needs and priorities of the watershed plan.

Nonpoint Source Versus Point Source

Although watershed plans typically focus on nonpoint sources, they should consider and integrate point sources for effective watershed protection. You should separate nonpoint

sources from point sources for assessment for both technical and programmatic reasons. Nonpoint and point sources typically behave differently and affect the receiving waters under different conditions. For example, nonpoint sources usually contribute pollutant loads that are washed off and transported during precipitation events, affecting waterbody conditions during times of higher surface runoff and, therefore, higher flow. Point sources usually discharge constant loads to receiving waters, affecting waterbody conditions during times of low flow when there is less water to dilute incoming effluents. Not only do point and nonpoint sources behave and affect waterbodies differently, but their management and control mechanisms are also different. Grouping them separately when considering future implementation of control measures is logical.

Spatial Distribution and Location

Grouping sources by location facilitates their assessment by dividing the area of concern into smaller, more focused areas, and it often supports future implementation. Spatially grouping sources helps to identify priority regions or locations that should be targeted for control. The method of grouping sources typically involves creating subwatersheds within the larger watershed of concern and also prioritizing sources within the subwatershed by some other methodology (e.g., proximity to a stream, land use).

Land Use Distribution

Sources are often specific to certain land uses, making it logical to group them by land use. For example, sources of nutrients such as livestock grazing and fertilizer application, which occur in conjunction with agricultural land use, would not likely contribute the same loads as other land uses such as urban or forest uses. Likewise, urban land uses typically have a set of pollutants of concern (e.g., metals, oil, sediment) different from those of rural land uses based on the active sources. Although it is difficult to isolate inputs from individual sources within a land use, assessing them as land use inputs can still support evaluation of loading and identification of future controls. Sources can be grouped and characterized by land use at a large scale, such as all agricultural lands, or at a very detailed level, such as specific crop type. In some cases, subcategories of nonpoint sources should be used to estimate the source contribution. For example, a land use like agriculture would often be further broken down into grazing or cropland, allowing a more accurate estimate of the sources coming from each subcategory and the ability to choose the most effective management practices for each subcategory.

Grouping sources according to their land use also facilitates identification of future implementation efforts because certain management practices are most effective when applied to a certain land use.

Delivery Pathway and Behavior

Nonpoint sources, depending on their behavior, can contribute pollutants to receiving waters through different delivery pathways. The nature of the delivery might support separate assessment of the source. For example, grazing cattle might be treated as a separate source depending on the activity or location of the cattle. Livestock on rangeland can contribute pollutants to the land that are picked up in runoff, whereas livestock in streams deposit nutrient and bacteria loads directly to the streams. Different methods might be required to

evaluate the effect of each group on waterbody conditions. Another example is failing septic systems that might be contributing pollutant loads to waterbodies. Because loads from the septic systems can be delivered through ground water and also through surface breakouts, you might decide to conduct separate analyses to estimate their loads.

Other Factors

Additional factors that can influence the grouping of sources include the following:

- **Social and economic factors.** Certain sources and their impact might be of higher priority to the affected public because they are more visible than other sources or because they could have negative impacts on the local economy. Public buy-in and priorities can influence the evaluation and grouping of sources, as well as subsequent source control.
- **Political jurisdictions.** Because source control can ultimately fall to different jurisdictions (e.g., counties), it might be necessary to evaluate sources based in part on jurisdictional boundaries. In some cases, the sources might even be subject to different laws and control options, depending on where they're located.

7.3.2 Time Frame for Source Assessment

Another important consideration when deciding how to quantify your sources is the time frame you want to capture. Your data analysis should provide insight into the timing of watershed problems and, therefore, into the temporal scale you need to evaluate sources. For example, instream dissolved oxygen might decrease only during summer months because of increased nutrient loading, higher temperatures, and lower flows. Therefore, it will be important to characterize and quantify sources on a time scale that allows for evaluation during the summer months. It would not be appropriate to evaluate annual loading for a problem that occurs only during the summer.

7.4 Summarize Causes and Sources

⑨ On the basis of your data analysis, you should now be able to identify the key sources you will quantify in the next step of the watershed planning process (elements a and b). You should identify the source type, locations, and timing for load estimation (↪ chapter 8). It might be helpful to identify the areas for evaluation on a watershed map to determine the key locations for conducting the loading analysis and which sources will be included in the analysis. You should also develop a brief report summarizing your data analyses and their results and describing the watershed sources, including their location, associated pollutants, timing, and impact on the waterbody.

⑨ In identifying your sources and grouping them for load estimation, you'll also begin to identify the critical areas needed for implementing management measures, as required as element c of the nine minimum elements. Element c is "*A description of the nonpoint source management measures that will need to be implemented to achieve load reductions and a description of the critical areas in which those measures will be needed to implement this plan.*" At this step, you have identified the recommended source groupings and priorities and you'll continue to refine the groupings as you conduct your loading analysis (↪ chapter 8) and target your management measures (↪ chapters 10 and 11). You'll identify the final critical areas when you select the management strategies for implementing your plan (↪ chapter 11), but the sources and associated groupings and characteristics you have identified at this stage will provide the basis and groundwork for identifying those critical areas.

ATTACHMENT 54

Chapter 5 Stormwater Management Approaches

A fundamental component of the U.S. Environmental Protection Agency's (EPA) Stormwater Program, for municipalities as well as industries and construction, is the creation of stormwater pollution prevention plans. These plans invariably document the stormwater control measures that will be used to prevent the permittee's stormwater discharges from degrading local waterbodies. Thus, a consideration of these measures—their effectiveness in meeting different goals, their cost, and how they are coordinated with one another—is central to any evaluation of the Stormwater Program. This report uses the term stormwater control measure (SCM) instead of the term best management practice (BMP) because the latter is poorly defined and not specific to the field of stormwater.

The committee's statement of task asks for an evaluation of the relationship between different levels of stormwater pollution prevention plan implementation and in-stream water quality. As discussed in the last two chapters, the state of the science has yet to reveal the mechanistic links that would allow for a full assessment of that relationship. However, enough is known to design systems of SCMs, on a site scale or local watershed scale, to lessen many of the effects of urbanization. Also, for many regulated entities the current approach to stormwater management consists of choosing one or more SCMs from a preapproved list. Both of these facts argue for the more comprehensive discussion of SCMs found in this chapter, including information on their characteristics, applicability, goals, effectiveness, and cost. In addition, a multitude of case studies illustrate the use of SCMs in specific settings and demonstrate that a particular SCM can have a measurable positive effect on water quality or a biological metric. The discussion of SCMs is organized along the gradient from the rooftop to the stream. Thus, pollutant and runoff prevention are discussed first, followed by runoff reduction and finally pollutant reduction.

HISTORICAL PERSPECTIVE ON STORMWATER CONTROL MEASURES

Over the centuries, SCMs have met different needs for cities around the world. Cities in the Mesopotamian Empire during the second millennium BC had practices for flood control, to convey waste, and to store rain water for household and irrigation uses (Manor, 1966) (see Figure 5-1). Today, SCMs are considered a vital part of managing flooding and drainage problems in a city. What is relatively new is an emphasis on using the practices to remove pollutants from stormwater and selecting practices capable of providing groundwater recharge. These recent expectations for SCMs are not readily accepted and require an increased commitment to the proper design and maintenance of the practices.

With the help of a method for estimating peak flows (the Rational Method, see Chapter 4), the modern urban drainage system came into being soon after World War II. This generally consisted of a system of catch basins and pipes to prevent flooding and drainage problems by efficiently delivering runoff water to the nearest waterbody. However, it was soon realized that delivering the water too quickly caused severe downstream flooding and bank erosion in the receiving water. To prevent bank erosion and provide more space for flood waters, some stream channels were enlarged and lined with concrete (see Figure 5-2). But while hardening and

FIGURE 5-1 Cistern tank, Kamiros, Rhodes (ancient Greece, 7th century BC). SOURCE: Robert Pitt.

FIGURE 5-2 Concrete channel in Lincoln Creek, Milwaukee, Wisconsin. SOURCE: Roger Bannerman.

enlarging natural channels is a cost-effective solution to erosion and flooding, the modified channel increases downstream peak flows and it does not provide habitat to support a healthy aquatic ecosystem.

Some way was needed to control the quantity of water reaching the end of pipes during a runoff event, and on-site detention (Figure 5-3) became the standard for accomplishing this. Ordinances started appearing in the early 1970s, requiring developers to reduce the peaks of different size storms, such as the 10-year, 24-hour storm. The ordinances were usually intended to prevent future problems with peak flows by requiring the installation of flow control structures, such as detention basins, in new developments. Detention basins can control peak flows directly below the point of discharge and at the property boundary. However, when designed on a site-by-site basis without taking other basins into account, they can lead to downstream flooding problems because volume is not reduced (McCuen, 1979; Ferguson, 1991; Traver and Chadderton, 1992; EPA, 2005d). In addition, out of concerns for clogging, openings in the outlet structure of most basins are generally too large to hold back flows from smaller, more frequent storms. Furthermore, low-flow channels have been constructed or the basins have been graded to move the runoff through the structure without delay to prevent wet areas and to make it easier to mow and maintain the detention basin.

Because of the limitations of on-site detention, infiltration of urban runoff to control its volume has become a recent goal of stormwater management. Without stormwater infiltration, municipalities in wetter regions of the country can expect drops in local groundwater levels, declining stream base flows (Wang et al., 2003a), and flows diminished or stopped altogether from springs feeding wetlands and lakes (Leopold, 1968; Ferguson, 1994).

The need to provide volume control marked the beginning of low-impact development (LID) and conservation design (Arendt, 1996; Prince George's County, 2000), which were founded on the seminal work of landscape architect Ian McHarg and associates decades earlier (McHarg and Sutton, 1975; McHarg and Steiner, 1998). The goal of LID is to allow for development of a site while maintaining as much of its natural hydrology as possible, such as infiltration, frequency and volume of discharges, and groundwater recharge. This is accomplished with infiltration practices, functional grading, open channels, disconnection of

FIGURE 5-3. On-site detention. SOURCE: Tom Schueler.

impervious areas, and the use of fewer impervious surfaces. Much of the LID focus is to manage the stormwater as close as possible to its source—that is, on each individual lot rather than conveying the runoff to a larger regional SCM. Individual practices include rain gardens (see Figure 5-4), disconnected roof drains, porous pavement, narrower streets, and grass swales. In some cases, LID site plans still have to include a method for passing the larger storms safely, such as a regional infiltration or detention basin or by increasing the capacity of grass swales.

Infiltration has been practiced in a few scattered locations for a long time. For example, on Long Island, New York, infiltration basins were built starting in 1930 to reduce the need for a storm sewer system and to recharge the aquifer, which was the only source of drinking water (Ferguson, 1998). The Cities of Fresno, California, and El Paso, Texas, which faced rapidly dropping groundwater tables, began comprehensive infiltration efforts in the 1960s and 1970s. In the 1980s Maryland took the lead on the east coast by creating an ambitious statewide infiltration program. The number of states embracing elements of LID, especially infiltration, has increased during the 1990s and into the new century and includes California, Florida, Minnesota, New Jersey, Vermont, Washington, and Wisconsin.

FIGURE 5-4 Rain Garden in Madison, Wisconsin. SOURCE: Roger Bannerman.

Evidence gathered in the 1970s and 1980s suggested that pollutants be added to the list of things needing control in stormwater (EPA, 1983). Damages caused by elevated flows, such as stream habitat destruction and floods, were relatively easy to document with something as simple as photographs. Documentation of elevated concentrations of conventional pollutants and potentially toxic pollutants, however, required intensive collection of water quality samples during runoff events. Samples collected from storm sewer pipes and urban streams in the Menomonee River watershed in the late 1970s clearly showed the concentrations of many pollutants, such as heavy metals and sediment, were elevated in urban runoff (Bannerman et al., 1979). Levels of heavy metals were especially high in industrial-site runoff, and construction-site erosion was calculated to be a large source of sediment in the watershed. This study was followed by the National Urban Runoff Program, which added more evidence about the high levels of some pollutants found in urban runoff (Athayde et al., 1983; Bannerman et al., 1983).

PREPUBLICATION

With new development rapidly adding to the environmental impacts of existing urban areas, the need to develop good stormwater management programs is more urgent than ever. For a variety of reasons, the greatest potential for stormwater management to reduce the footprint of urbanization is in the suburbs. These areas are experiencing the fastest rates of growth, they are more amenable to stormwater management because buildings and infrastructure are not yet in place, and costs for stormwater management can be borne by the developer rather than by taxpayers. Indeed, most structural SCMs are applied to new development rather than existing urban areas. Many of the most innovative stormwater programs around the country are found in the suburbs of large cities such as Seattle, Austin, and Washington, D.C. When stormwater management in ultra-urban areas is required, it entails the retrofitting of detention basins and other flow control structures or the introduction of innovative below-ground structures characterized by greater technical constraints and higher costs, most of which are charged to local taxpayers.

Current-day SCMs represent a radical departure from past practices, which focused on dealing with extreme flood events via large detention basins designed to reduce peak flows at the downstream property line. As defined in this chapter, SCMs now include practices intended to meet broad watershed goals of protecting the biology and geomorphology of receiving waters in addition to flood peak protection. The term encompasses such diverse actions as using more conventional practices like basins and wetland to installing stream buffers, reducing impervious surfaces, and educating the public.

REVIEW OF STORMWATER CONTROL MEASURES

Stormwater control measures refer to what is defined by EPA (1999) as “a technique, measure, or structural control that is used for a given set of conditions to manage the quantity and improve the quality of stormwater runoff in the most cost-effective manner.” SCMs are designed to mitigate the changes to both the quantity and quality of stormwater runoff that are caused by urbanization. Some SCMs are engineered or constructed facilities, such as a stormwater wetland or infiltration basin, that reduce pollutant loading and modify volumes and flow. Other SCMs are preventative, including such activities as education and better site design to limit the generation of stormwater runoff or pollutants.

Stormwater Management Goals

It is impossible to discuss SCMs without first considering the goals that they are expected to meet. A broadly stated goal for stormwater management is to reduce pollutant loads to waterbodies and maintain, as much as possible, the natural hydrology of a watershed. On a practical level, these goals must be made specific to the region of concern and embedded in the strategy for that region. Depending on the designated uses of the receiving waters, climate, geomorphology, and historical development, a given area may be more or less sensitive to both pollutants and hydrologic modifications. For example, goals for groundwater recharge might be higher in an area with sandy soils as compared to one with mostly clayey soils; watersheds in the coastal zone may not require hydrologic controls. Ideally, the goals of stormwater management should be linked to the water quality standards for a given state's receiving waters. However,

because of the substantial knowledge gap about the effect of a particular stormwater discharge on a particular receiving water (see Chapter 3 conclusions), surrogate goals are often used by state stormwater programs in lieu of water quality standards. Examples include credit systems, mandating the use of specific SCMs, or achieving stormwater volume reduction. Credit systems might be used for practices that are known to be productive but are difficult to quantify, such as planting trees. Specific SCMs might be assumed to remove a percent of pollutants, for example 85 percent removal of total suspended solids (TSS) within a stormwater wetland. Reducing the volume of runoff from impervious surfaces (e.g., using an infiltration device) might be assumed to capture the first flush of pollutants during a storm event. Before discussing specific state goals, it is worth understanding the broader context in which goals are set.

Trade-offs Between Stormwater Control Goals and Costs

The potentially substantial costs of implementing SCMs raise a number of fundamental social choices concerning land-use decisions, designated uses, and priority setting for urban waters. To illustrate some of these choices, consider a hypothetical urban watershed with three possible land-cover scenarios: 25, 50, and 75 percent impervious surface. A number of different beneficial uses could be selected for the streams in this watershed. At a minimum, the goal may be to establish low-level standards to protect public health and safety. To achieve this, sufficient and appropriate SCMs might be applied to protect residents from flooding and achieve water quality conditions consistent with secondary human contact. Alternatively, the designated use could be to achieve the physical, chemical, and/or biological conditions sufficient to provide exceptional aquatic habitat (e.g., a high-quality recreational fishery). The physical, biological, and chemical conditions supportive of this use might be similar to a reference stream located in a much less disturbed watershed. Achieving this particular designated use would require substantially greater resources and effort than achieving a secondary human contact use. Intermediate designated uses could also be imagined, including improving ambient water quality conditions that would make the water safe for full-body emersion (primary human contact) or habitat conditions for more tolerant aquatic species.

Figure 5-5 sketches what the marginal (incremental) SCM costs (opportunity costs) might be to achieve different designated uses given different amounts of impervious surface in the watershed. The horizontal axis orders potential designated uses in terms of least difficult to most difficult to achieve. The three conceptual curves represent the SCM costs under three different impervious surface scenarios. The relative positions of the cost curves indicate that achieving any specific designated use will be more costly in situations with a higher percentage of the watershed in impervious cover. All cost curves are upward sloping, reflecting the fact that incremental improvements in designated uses will be increasingly costly to achieve. The cost curves are purely conceptual, but nonetheless might reasonably reflect the relative costs and direction of change associated with achieving specific designated uses in different watershed conditions.

The locations of the cost curves suggest that in certain circumstances not all designated uses can be achieved or can be achieved only at an extremely high cost. For example, the attainment of exceptional aquatic uses may be unachievable in areas with 50 percent impervious surface even with maximum application of SCMs. In this illustration, the cost of achieving even secondary human contact use is high for areas with 75 percent impervious surfaces. In such

FIGURE 5-5 Cost of achieving designated uses in a hypothetical urban watershed. MCC is the marginal control cost, which represents the incremental costs to achieve successive expansion of designated uses through SCMs. The curves are constructed on the assumption that the lowest cost combination of SCMs would be implemented at each point on the curve.

highly urbanized settings, achievement of only adequate levels of aquatic uses could be exceedingly high and strain the limits of what is technically achievable. Finally, the existing and likely expected future land-use conditions have significant implications for what is achievable and at what cost. Clearly land-use decisions have an impact on the cost and whether a use can be achieved, and thus they need to be included in the decision process. The trade-off between costs and achieving specific designated uses can change substantially given different development patterns.

The purpose of Figure 5-5 is not to identify the precise location of the cost curves or to identify thresholds for achieving specific designated uses. Rather, these concepts are used to illustrate some fundamental trade-offs that confront public and private investment and regulatory decisions concerning stormwater management. The general relationships shown in Figure 5-5 suggest the need for establishing priorities for investments in stormwater management and controls, and connecting land usage and watershed goals. Setting overly ambitious or costly goals for urban streams may result in the perverse consequence of causing more waters to fail to meet designated uses. For example, consider efforts to secure ambitious designated uses in highly developed areas or in an area slated for future high-density development. Regulatory requirements and investments to limit stormwater quantity and quality through open-space requirements, areas set aside for infiltration and water detention, and strict application of maximum extent practicable controls have the effect of both increasing development costs and diminishing land available for residential and commercial properties. Policies designed to achieve exceedingly costly or infeasible designated uses in urban or urbanizing areas could have the net consequence of shifting development (and associated impervious surface) out into neighboring areas and watersheds. The end result might be minimal improvements in “within-watershed” ambient conditions but a decrease in designated uses (more impairments) elsewhere.

In such a case, it might be sound water quality policy to accept higher levels of impervious surface in targeted locations, more stormwater-related impacts, and less ambitious designated uses in urban watersheds in order to preserve and protect designated uses in other watersheds.

Setting unrealistic or unachievable water quality objectives in urban areas can also pose political risks for stormwater management. The cost and difficulty of achieving ambitious water quality standards for urban stream goals may be understood by program managers but pursued nonetheless in efforts to demonstrate public commitment to achieving high-quality urban waters. Yet, promising what cannot be realistically achieved may act to undermine public support for urban stormwater programs. Increasing costs without significant observable improvements in ambient water conditions or achievement of water quality standards could ultimately reduce public commitment to the program. Thus, there are risks of “setting the bar” too high, or not coordinating land use and designated stream uses.

The cost of setting the bar too low can also be significant. Stormwater requirements that result in ineffective stormwater management will not achieve or maintain the desired water uses and can result in impairments. Loss of property, degraded waters, and failed infrastructure are tangible costs to the public (Johnston et al., 2006). Streambank rehabilitation costs can be severe, and loss of confidence in the ability to meet stormwater goals can result.

The above should not be construed as an argument for or against devoting resources to SCMs; rather, such decisions should be made with an open and transparent acknowledgment and understanding of the costs and consequences involved in those decisions.

Common State Stormwater Goals

Most states do not and have never had an overriding water quality objective in their stormwater program, but rather have used engineering criteria for SCM performance to guide stormwater management. These criteria can be loosely categorized as

- Erosion and sedimentation control,
- Recharge/base flow,
- Water quality,
- Channel protection, and
- Flooding events.

The SCMs used to address these goals work by minimizing or eliminating increases in stormwater runoff volume, peak flows, and/or the pollutant load carried by stormwater.

The criteria chosen by any given state usually integrate state, federal, and regional laws and regulations. Areas of differing climates may emphasize one goal over another, and the levels of control may vary drastically. Contrast a desert region where rainwater harvesting is extremely important versus a coastal region subject to hurricanes. Some areas like Seattle have frequent smaller volume rainfalls—the direct opposite of Austin, Texas—such that small volume controls would be much more effective in Seattle than Austin. Regional geology (karst) or the presence of Brownfields may affect the chosen criteria as well.

The committee’s survey of State Stormwater Programs (Appendix C) reflects a wide variation in program goals as reflected in the criteria found in their SCM manuals. Some states have no specific criteria because they do not produce SCM manuals, while others have manuals that address every category of criteria from flooding events to groundwater recharge. Some states rely upon EPA or other states’ or transportation agencies’ manuals. In general, soil and

erosion control criteria are the most common and often exist in the absence of any other state criteria. This wide variation reflects the difficulties that states face in keeping up with rapidly changing information about SCM design and performance.

The criteria are ordered below (after the section on erosion and sediment control) according to the size of the storm they address, from smallest to most extreme. The criteria can be expressed in a variety of ways, from a simple requirement to control a certain volume of rainfall or runoff (expressed as a depth) to the size of a design storm to more esoteric requirements, such as limiting the time that flow can be above a certain threshold. The volumes of rainfall or runoff are based on statistics of a region's daily rainfall, and they approximate one another as the percentage of impervious cover increases. Design storms for larger events that address channel protection and flooding are usually based on extreme event statistics and tend to represent a temporal pattern of rainfall over a set period, usually a day. Finally, it should be noted that the categories are not mutually exclusive; for example, recharge of groundwater may enhance water quality via pollutant removal during the infiltration process.

Erosion and Sedimentation Control. This criterion refers to the prevention of erosion and sedimentation of sites during construction and is focused at the site level. Criteria usually include a barrier plan to prevent sedimentation from leaving the site (e.g., silt fences), practices to minimize the potential erosion (phased construction), and facilities to capture and remove sediment from the runoff (detention). Because these measures are considered temporary, smaller extreme events are designated as the design storm than what typically would be used if flood control were the goal.

Recharge/Base Flow. This criterion is focused on sustaining the preconstruction hydrology of a site as it relates to base flow and recharge of groundwater supplies. It may also include consideration of water usage of the property owners and return through septic tanks and tile fields. The criterion, expressed as a volume requirement, is usually to capture around 0.5 to 1.0 inch of runoff from impervious surfaces depending on the climate and soil type of the region. (For this range of rainfall, very little runoff occurs from grass or forested areas, which is why runoff from impervious surfaces is used as the criterion.)

Water Quality. Criteria for water quality are the most widespread, and are usually crafted as specific percent removal for pollutants in stormwater discharge. Generally, a water quality criterion is based on a set volume of stormwater being treated by the SCM. The size of the storm can run from the first inch of rainfall off impervious surfaces to the runoff from the one-year, 24-hour extreme storm event. It should be noted that the term "water quality" covers a wide range of groundwater and surface water pollutants, including water temperature and emerging contaminants.

Many of the water quality criteria are surrogates for more meaningful parameters that are difficult to quantify or cannot be quantified, or they reflect situations where the science is not developed enough to set more explicit goals. For example, the Wisconsin state requirement of an 80 percent reduction in TSS in stormwater discharge does not apply to receiving waters themselves. However, it presumes that there will be some water quality benefits in receiving waters; that is, phosphorus and fecal coliform might be captured by the TSS requirement. Similarly water quality criteria may be expressed as credits for good practices, such as using LID, street sweeping, or stream buffers.

Channel Protection. This criterion refers to protecting channels from accelerated erosion during storm events due to the increased runoff. It is tied to either the presumed “channel-forming event”—what geomorphologists once believed was the storm size that created the channel due to erosion and deposition—or to the minimum flow that accomplishes any degree of sediment transport. It is generally defined as somewhere between the one- and five-year, 24-hour storm event or a discharge level typically exceeded once to several times per year. Some states require a reduction in runoff volume for these events to match preconstruction levels. Others may require that the average annual duration of flows that are large enough to erode the streambank be held the same on an annual basis under pre- and postdevelopment conditions.

It is not uncommon to find states where a channel protection goal will be written poorly, such that it does not actually prevent channel widening. For example, MacRae (1997) presented a review of the common “zero runoff increase” discharge criterion, which is commonly met by using ponds designed to detain the two-year, 24-hour storm. MacRae showed that stream bed and bank erosion occur during much lower events, namely mid-depth flows that generally occur more often than once a year, not just during bank-full conditions (approximated by the two-year event). This finding is entirely consistent with the well-established geomorphological literature (e.g., Pickup and Warner, 1976; Andrews, 1984; Carling, 1988; Sidle, 1988). During monitoring near Toronto, MacRae found that the duration of the geomorphically significant predevelopment mid-bankfull flows increased by more than four-fold after 34 percent of the basin had been urbanized. The channel had responded by increasing in cross-sectional area by as much as three times in some areas, and was still expanding.

Flooding Events. This criterion addresses public safety and the protection of property and is applicable to storm events that exceed the channel capacity. The 10- through the 100-year storm is generally used as the standard. Volume-reduction SCMs can aid or meet this criterion depending on the density of development, but usually assistance is needed in the form of detention SCMs. In some areas, it may be necessary to reduce the peak flow to below preconstruction levels in order to avoid the combined effects of increased volume, altered timing, and a changed hydrograph. It should be noted that some states do not consider the larger storms (100-year) to be a stormwater issue and have separate flood control requirements.

Each state develops a framework of goals, and the corresponding SCMs used to meet them, which will depend on the scale and focus of the stormwater management strategy. A few states have opted to express stormwater goals within the context of watershed plans for regions of the state. However, the setting of goals on a watershed basis is time-consuming and requires study of the watersheds in question. The more common approach has been to set generic or minimal controls for a region that are not based on a watershed plan. This has been done in Maryland, Wisconsin (see Box 5-1), and Pennsylvania (see Box 5-2). This strategy has the advantage of more rapid implementation of some SCMs because watershed management plans are not required. In order to be applicable to all watersheds in the state, the goals must target common pollutants or flow modification factors where the processes are well known. It must also be possible for these goals to be stated in National Pollutant Discharge Elimination System (NPDES) permits. Many states have selected TSS reduction, volume reduction, and peak flow control as generic goals. A generic goal is not usually based on potentially toxic pollutants, such as heavy metals, due to the complexity of their interaction in the environment, the dependence on

BOX 5-1

Wisconsin Statewide Goal of TSS Reduction for Stormwater Management

To measure the success of stormwater management, Wisconsin has statewide goals for sediment and flow (Wisconsin DNR, 2002). A lot is known about the impacts of sediment on receiving waters, and any reduction is thought to be beneficial. Flow can be a good indicator of other factors; for example, reducing peak flows will prevent bank erosion.

Developing areas in Wisconsin are required to reduce the annual TSS load by 80 percent compared to no controls (Wisconsin DNR, 2002). Two flow-rated requirements for developing areas are in the administrative rules. One is that the site must maintain the peak flow for the two-year, 24-hour rainfall event. Second, the annual infiltration volume for postdevelopment must be within 90 percent of the predevelopment volumes for residential land uses; the number for non-residential is 60 percent. Both of these flow control goals are thought to also have water quality benefits.

The goal for existing urban areas is an annual reduction in TSS loads. Municipalities must reduce their annual TSS loads by 20 percent, compared to no controls, by 2008. This number is increased to 40 percent by 2013. All of these goals were partially selected to be reasonable based on cost and technical feasibility.

BOX 5-2

Volume-Based Stormwater Goals in Pennsylvania

Pennsylvania has developed a stormwater *Best Management Practices* manual to support the Commonwealth's Storm Water Management Act. This manual and an accompanying sample ordinance advocates two methods for stormwater control based on volume, termed Control Guidance (CG) 1 and 2. The first (CG-1) requires that the runoff volume be maintained at the two-year, 24-hour storm level (which corresponds to approximately 3.5 inches of rainfall in this region) through infiltration, evapotranspiration, or reuse. This criterion addresses recharge/base flow, water quality, and channel protection, as well as helping to meet flooding requirements.

The second method (CG-2) requires capture and removal of the first inch of runoff from paved areas, with infiltration strongly recommended to address recharge and water quality issues. Additionally, to meet channel protection criteria, the second inch is required to be held for 24 hours, which should reduce the channel-forming flows. (This is an unusual criterion in that it is expressed as what an SCM can accomplish, not as the flow that the channel can handle.) Peak flows for larger events are required to be at preconstruction levels or less if the need is established by a watershed plan. These criteria are the starting point for watershed or regional plans, to reduce the effort of plan development. Some credits are available for tree planting, and other nonstructural practices are advocated for dissolved solids mitigation. See <http://www.dep.state.pa.us/dep/deputate/watermgt/wc/subjects/stormwatermanagement/default.htm>.

the existing baseline conditions, and the need for more understanding on what are acceptable levels. The difficulty with the generic approach is that specific watershed issues are not addressed, and the beneficial uses of waters are not guaranteed.

One potential drawback of a strategy based on a generic goal coupled to the permit process is that the implementation of the goal is usually on a site-by-site basis, especially for developing areas. Generic goals may be appropriate for certain ubiquitous watershed processes and are clearly better than having no goals at all. However, they do not incorporate the effects of differences in past development and any unique watershed characteristics; they should be considered just a good starting point for setting watershed-based goals.

Role of SCMs in Achieving Stormwater Management Goals

One important fundamental change in SCM design philosophy has come about because of the recent understanding of the roles of smaller storms and of impervious surfaces. This is demonstrated by Box 3-4, which shows that for the Milwaukee area more than 50 percent of the rainfall by volume occurs in storms that have a depth of less than 0.75 inch. If extreme events are the only design criteria for SCMs, the vast majority of the annual rainfall will go untreated or uncontrolled, as it is smaller than the minimum extreme event. This relationship is not the same in all regions. For example, in Austin, Texas, the total yearly rainfall is smaller than in Milwaukee, but a large part of the volume occurs during larger storm events, with long dry periods in between.

The upshot is that the design strategy for stormwater management, including drainage systems and SCMs, should take a region's rainfall and associated runoff conditions into account. For example, an SCM chosen to capture the majority of the suspended solids, recharge the baseflow, reduce streambank erosion, and reduce downstream flooding in Pennsylvania or Seattle (which have moderate and regular rainfall) would likely not be as effective in Texas, where storms are infrequent and larger. In some areas, a reduction in runoff volume may not be sufficient to control streambank erosion and flooding, such that a second SCM like an extended detention stormwater wetland may be needed to meet management goals.

Finally, as discussed in greater detail in a subsequent section, SCMs are most effective from the perspective of both efficiency and cost when stormwater management is incorporated in the early planning stages of a community. Retrofitting existing development with SCMs is much more technically difficult and costly because the space may not be available, other infrastructure is already installed, or utilities may interfere. Furthermore, if the property is on private land or dedicated as an easement to a homeowners association, there may be regulatory limitations to what can be done. Because of these barriers, retrofitting existing urban areas often depends on engineered or manufactured SCMs, which are more expensive in both construction and operation.

Stormwater Control Measures

SCMs reduce or mitigate the generation of stormwater runoff and associated pollutants. These practices include both "structural" or engineered devices as well as more "nonstructural measures" such as land-use planning, site design, land conservation, education, and stewardship practices. Structural practices may be defined as any facility constructed to mitigate the adverse impacts of stormwater and urban runoff pollution. Nonstructural practices, which tend to be longer-term and lower-maintenance solutions, can greatly reduce the need for or increase the effectiveness of structural SCMs. For example, product substitution and land-use planning may be key to the successful implementation of an infiltration SCM. Preserving wooded areas and reducing street widths can allow the size of detention basins in the area to be reduced.

Table 5-1 presents the expansive list of SCMs that are described in this chapter. For most of the SCMs, each listed item represents a class of related practices, with individual methods discussed in greater detail later in the chapter. There are nearly 20 different broad categories of SCMs that can be applied, often in combination, to treat the quality and quantity of stormwater runoff. A primary difference among the SCMs relates to which stage of the development cycle

they are applied, where in the watershed they are installed, and who is responsible for implementing them.

The development cycle extends from broad planning and zoning to site design, construction, occupancy, retrofitting, and redevelopment. As can be seen, SCMs are applied throughout the entire cycle. The scale at which the SCM is applied also varies considerably. While many SCMs are installed at individual sites as part of development or redevelopment applications, many are also applied at the scale of the stream corridor or the watershed or to existing municipal stormwater infrastructure. The final column in Table 5-1 suggests who would implement the SCM. In general, the responsibility for implementing SCMs primarily resides with developers and local stormwater agencies, but planning agencies, landowners, existing industry, regulatory agencies, and municipal separate storm sewer system (MS4) permittees can also be responsible for implementing many key SCMs.

In Table 5-1, the SCMs are ordered in such a way as to mimic natural systems as rain travels from the roof to the stream through combined application of a series of practices throughout the entire development site. This order is upheld throughout the chapter, with the implication that no SCM should be chosen without first considering those that precede it on the list.

Given that there are 20 different SCM groups and a much larger number of individual design variations or practices within each group, it is difficult to authoritatively define the specific performance or effectiveness of SCMs. In addition, our understanding of their performance is rapidly changing to reflect new research, testing, field experience, and maintenance history. The translation of these new data into design and implementation guidance is accelerating as well. What is possible is to describe their basic hydrologic and water quality objectives and make a general comparative assessment of what is known about their design, performance, and maintenance as of mid-2008. This broad technology assessment is provided in Table 5-2, which reflects the committee's collective understanding about the SCMs from three broad perspectives:

- Is widely accepted design or implementation guidance available for the SCM and has it been widely disseminated to the user community?
- Have enough research studies been published to accurately characterize the expected hydrologic or pollutant removal performance of the SCM in most regions of the country?
- Is there enough experience with the SCM to adequately define the type and scope of maintenance needed to ensure its longevity over several decades?

Affirmative answers to these three questions are needed to be able to reliably quantify or model the ability of the SCM, which is an important element in defining whether the SCM can be linked to improvements in receiving water quality. As will be discussed in subsequent sections of this chapter, there are many SCMs for which there is only a limited understanding, particularly those that are nonstructural in nature.

The columns in Table 5-2 summarize several important factors about each SCM, including the ability of the SCM to meet hydrologic control objectives and water quality objectives, the availability of design guidance, the availability of performance studies, and whether there are maintenance protocols. The hydrologic control objectives range from complete prevention of stormwater flow to reduction in runoff volume and reduction in peak flows. The column on water quality objectives describes whether the SCM can prevent the generation of, or remove, contaminants of concern in stormwater.

TABLE 5-1 Summary of Stormwater Control Measures—When, Where, and Who

Stormwater Control Measure	When	Where	Who
<i>Product Substitution</i>	Continuous	National, state, regional	Regulatory agencies
<i>Watershed and Land-Use Planning</i>	Planning stage	Watershed	Local planning agencies
<i>Conservation of Natural Areas</i>	Site and watershed planning stage	Site, watershed	Developer, local planning agency
<i>Impervious Cover Minimization</i>	Site planning stage	Site	Developer, local review authority
<i>Earthwork Minimization</i>	Grading plan	Site	Developer, local review authority
Erosion and Sediment Control	Construction	Site	Developer, local review authority
<i>Reforestation and Soil Conservation</i>	Site planning and construction	Site	Developer, local review authority
<i>Pollution Prevention SCMs for Stormwater Hotspots</i>	Post-construction or retrofit	Site	Operators and local and state permitting agencies
Runoff Volume Reduction—Rainwater harvesting	Post-construction or retrofit	Rooftop	Developer, local planning agency and review authority
Runoff Volume Reduction—Vegetated	Post-construction or retrofit	Site	Developer, local planning agency and review authority
Runoff Volume Reduction—Subsurface	Post-construction or retrofit	Site	Developer, local planning agency and review authority
Peak Reduction and Runoff Treatment	Post-construction or retrofit	Site	Developer, local planning agency and review authority
Runoff Treatment	Post-construction or retrofit	Site	Developer, local planning agency and review authority
<i>Aquatic Buffers and Managed Floodplains</i>	Planning, construction and post-construction	Stream corridor	Developer, local planning agency and review authority, landowners
Stream Rehabilitation	Postdevelopment	Stream corridor	Local planning agency and review authority
<i>Municipal Housekeeping</i>	Postdevelopment	Streets and stormwater infrastructure	MS4 Permittee
<i>Illicit Discharge Detection and Elimination</i>	Postdevelopment	Stormwater infrastructure	MS4 Permittee
<i>Stormwater Education</i>	Postdevelopment	Stormwater infrastructure	MS4 Permittee
<i>Residential Stewardship</i>	Postdevelopment	Stormwater infrastructure	MS4 Permittee

Note: Nonstructural SCMs are in italics.

The availability of design guidance tends to be greatest for the structural practices. Some but not all nonstructural practices are of recent origin, and communities lack available design guidance to include them as an integral element of local stormwater solutions. Where design guidance is available, it may not yet have been disseminated to the full population of Phase II MS4 communities.

The column on the availability of performance data is divided into those SCMs where enough studies have been done to adequately define performance, those SCMs where limited work has been done and the results are variable, and those SCMs where only a handful of studies are available. A large and growing number of performance studies are available that report the efficiencies of structural SCMs in reducing flows and pollutant loading (Strecker et al., 2004; ASCE, 2007; Schueler et al., 2007; Selbig and Bannerman, 2008). Many of these are compiled in the Center for Watershed Protection's National Pollutant Removal Performance Database for Stormwater Treatment Practices (http://www.cwp.org/Resource_Library/Center_Docs/SW/bmpwriteup_092007_v3.pdf), in the International Stormwater BMP Database (<http://www.bmpdatabase.org/Docs/Performance%20Summary%20June%202008.pdf>), and by the Water Environment Research Foundation (WERF, 2008). In cases where there is incomplete understanding of their performance, often information can be gleaned from other fields including agronomy, forestry, petroleum exploration, and sanitary engineering. Current research suggests that it is not a question if whether structural SCMs "work" but more of a question of to what degree and with what longevity (Heasom et al., 2006; Davis et al., 2008; Emerson and Traver, 2008). There is considerably less known about the performance of nonstructural practices for stormwater treatment, partly because their application has been uneven around the country and it remains fairly low in comparison to structural stormwater practices.

Finally, defined maintenance protocols for SCMs can be nonexistent, emerging, or fully available. SCMs differ widely in the extent to which they can be considered permanent solutions. For those SCMs that work on the individual site scale on private property, such as rain gardens, local stormwater managers may be reluctant to adopt such practices due to concerns about their ability to enforce private landowners to conduct maintenance over time. Similarly, those SCMs that involve local government decisions (such as education, residential stewardship practices, zoning, or street sweeping) may be less attractive because governments are likely to change over time.

The following sections contain more detailed information about the individual SCMs listed in Tables 5-1 and 5-2, including the operating unit processes, the pollutants treated, the typical performance for both runoff and pollutant reduction, the strengths and weaknesses, maintenance and inspection requirements, and the largest sources of variability and uncertainty.

TABLE 5-2 Current Understanding of Stormwater Control Measure Capabilities

SCM	Hydrologic Control Objectives	Water Quality Objectives	Available Design Guidance	Performance Studies Available	Defined Maintenance Protocols
<i>Product Substitution</i>	NA	Prevention	NA	Limited	NA
<i>Watershed and Land-Use Planning</i>	All objectives	Prevention	Available	Limited	Yes
<i>Conservation of Natural Areas</i>	Prevention	Prevention	Available	None	Yes
<i>Impervious Cover Minimization</i>	Prevention and reduction	Prevention	Available	Limited	No
<i>Earthwork Minimization</i>	Prevention	Prevention	Emerging	Limited	Yes
Erosion and Sediment Control	Prevention and reduction	Prevention and removal	Available	Limited	Yes
<i>Reforestation and Soil Conservation</i>	Prevention and reduction	Prevention and removal	Emerging	None	No
<i>Pollution Prevention SCMs for Hotspots</i>	NA	Prevention	Emerging	Very few	No
Runoff Volume Reduction—Rainwater harvesting	Reduction	NA	Emerging	Limited	Yes
Runoff Volume Reduction—Vegetated (Green Roofs, Bioretention, Bioinfiltration, Bioswales)	Reduction and some peak attenuation	Removal	Available	Limited	Emerging
Runoff Volume Reduction—Subsurface (Infiltration Trenches, Pervious Pavements)	Reduction and some peak attenuation	Removal	Available	Limited	Yes
Peak Reduction and Runoff Treatment (Stormwater Wetlands, Dry/Wet Ponds)	Peak attenuation	Removal	Available	Adequate	Yes
Runoff Treatment (Sand Filters, Manufactured Devices)	None	Removal	Emerging	Adequate—sand filters Limited—manufactured devices	Yes

<i>Stormwater Education</i>	Prevention	Prevention	Available	Very few	Emerging
<i>Residential Stewardship</i>	Prevention	Prevention	Emerging	Very few	No

Note: Nonstructural SCMs are in italics.

Key:		
Hydrologic Objective	Water Quality Objective	Available Design Guidance?
Prevention: Prevents generation of runoff Reduction: Reduces volume of runoff Treatment: Delays runoff delivery	Prevention: Prevents generation, accumulation, or wash-off of pollutants and/or reduces runoff volume	Available: Basic design or implementation guidance is available in most areas of the country are readily available
Peak Attenuation: Reduction of peak flows through detention	Removal: Reduces pollutant concentrations in runoff by physical, chemical, or biological means	Emerging: Design guidance is still under development, is missing in many parts of the country, or requires more performance data
Performance Data Available?	Defined Maintenance Protocol?	Notes:
Very Few: Handful of studies, not enough data to generalize about SCM performance Limited: Numerous studies have been done, but results are variable or inconsistent Adequate: Enough studies have been done to adequately define performance	No: Extremely limited understanding of procedures to maintain SCM in the future Emerging: Still learning about how to maintain the SCM Yes: Solid understanding of maintenance for future SCM needs	NA: Not applicable for the SCM

Product Substitution

Product substitution refers to the classic pollution prevention approach of reducing the emissions of pollutants available for future wash-off into stormwater runoff. The most notable example is the introduction of unleaded gasoline, which resulted in an order-of-magnitude reduction of lead levels in stormwater runoff in a decade (Pitt et al., 2004a,b). Similar reductions are expected with the phase-out of methyl tert-butyl ether (MTBE) additives in gasoline. Other examples of product substitution are the ban on coal-tar sealants during parking lot renovation that has reduced PAH runoff (Van Metre et al., 2006), phosphorus-free fertilizers that have measurably reduced phosphorus runoff to Minnesota lakes (Barten and Johnson, 2007), the painting of galvanized metal surfaces, and alternative rooftop surfaces (Clark et al., 2005). Given the importance of coal power plant emissions in the atmospheric deposition of nitrogen and mercury, it is possible that future emissions reductions for such plants may result in lower stormwater runoff concentrations for these two pollutants.

The level of control afforded by product substitution is quite high if major reductions in emissions or deposition can be achieved. The difficulty is that these reductions require action in another environmental regulatory arena, such as air quality, hazardous waste, or pesticide regulations, which may not see stormwater quality as a core part of their mission.

Watershed and Land-Use Planning

Communities can address stormwater problems by making land-use decisions that change the location or quantity of impervious cover created by new development. This can be accomplished through zoning, watershed plans, comprehensive land-use plans, or Smart Growth incentives.

The unit process that is managed is the amount of impervious cover, which is strongly related to various residential and commercial zoning categories (Cappiella and Brown, 2000). Numerous techniques exist to forecast future watershed impervious cover and its probable impact on the quality of aquatic resources (see the discussion of the Impervious Cover Model in Chapter 3; CWP, 1998a; MD DNR, 2005). Using these techniques and simple or complex simulation models, planners can estimate stormwater flows and pollutant loads through the watershed planning process and alter the location or intensity of development to reduce them.

The level of control that can be achieved by watershed and land-use planning is theoretically high, but relatively few communities have aggressively exercised it. The most common application of downzoning has been applied to watersheds that drain to drinking water reservoirs (Kitchell, 2002). The strength of this practice is that it has the potential to directly address the underlying causes of the stormwater problem rather than just treating its numerous symptoms. The weakness is that local decisions on zoning and Smart Growth are reversible and often driven by other community concerns such as economic development, adequate infrastructure, and transportation. In addition, powerful consumer and market forces often have promoted low-density sprawl development. Communities that use watershed-based zoning often require a compelling local environmental goal, since state and federal regulatory authorities have traditionally been extremely reluctant to interfere with the local land-use and zoning powers.

Conservation of Natural Areas

Natural-area conservation protects natural features and environmental resources that help maintain the predevelopment hydrology of a site by reducing runoff, promoting infiltration, and preventing soil erosion. Natural areas are protected by a permanent conservation easement prescribing allowable uses and activities on the parcel and preventing future development. Examples include any areas of undisturbed vegetation preserved at the development site, including forests, wetlands, native grasslands, floodplains and riparian areas, zero-order stream channels, spring and seeps, ridge tops or steep slopes, and stream, wetland, or shoreline buffers. In general, conservation should maximize contiguous area and avoid habitat fragmentation.

While natural areas are conserved at many development sites, most of these requirements are prompted by other local, state, and federal habitat protections, and are not explicitly designed or intended to provide runoff reduction and stormwater treatment. To date, there are virtually no data to quantify the runoff reduction and/or pollutant removal capability of specific types of natural area conservation, or the ability to explicitly link them to site design.

Impervious Cover Reduction

A variety of practices, some of which fall under the broader term "better site design," can be used to minimize the creation of new impervious cover and disconnect or make more permeable the hard surfaces that are needed (Nichols et al., 1997; Richman, 1997; CWP, 1998a). A list of some common impervious cover reduction practices for both residential and commercial areas is provided below.

Elements of Better Site Design: Single-Family Residential

- Maximum residential street width
- Maximum street right-of-way width
- Swales and other stormwater practices can be located within the right-of-way
- Maximum cul-de-sac radius with a bioretention island in the center
- Alternative turnaround options such as hammerheads are acceptable if they reduce impervious cover
- Narrow sidewalks on one side of the street (or move pedestrian pathways away from the street entirely)
- Disconnect rooftops from the storm-drain systems
- Minimize driveway length and width and utilize permeable surfaces
- Allow for cluster or open-space designs that reduce lot size or setbacks in exchange for conservation of natural areas
- Permeable pavement in parking areas, driveways, sidewalks, walkways, and patios

Elements of Better Site Design: Multi-Family Residential and Commercial

- Design buildings and parking to have multiple levels
- Store rooftop runoff in green roofs, foundation planters, bioretention areas, or cisterns
- Reduce parking lot size by reducing parking demand ratios and stall dimensions
- Use landscaping areas, tree pits, and planters for stormwater treatment
- Use permeable pavement over parking areas, plazas, and courtyards

CWP (1998a) recommends minimum or maximum geometric dimensions for subdivisions, individual lots, streets, sidewalks, cul-de-sacs, and parking lots that minimize the generation of needless impervious cover, based on a national roundtable of fire safety, planning, transportation and zoning experts. Specific changes in local development codes can be made using these criteria, but it is often important to engage as many municipal agencies that are involved in development as possible in order to gain consensus on code changes.

At the present time, there is little research available to define the runoff reduction benefits of these practices. However, modeling studies consistently show a 10 to 45 percent reduction in runoff compared to conventional development (CWP, 1998b,c, 2002). Several monitoring studies have documented a major reduction in stormwater runoff from development sites that employ various forms of impervious cover reduction and LID in the United States and Australia (Coombes et al., 2000; Philips et al., 2003; Cheng et al., 2005) compared to those that do not.

Unfortunately, better site design has been slowly adopted by local planners, developers, designers, and public works officials. For example, although the project pictured in Figure 5-6 has been very successful in terms of controlling stormwater, the better-site-design principles used have not been widely adopted in the Seattle area. Existing local development codes may discourage or even prohibit the application of environmental site design practices, and many engineers and plan reviewers are hesitant to embrace them. Impervious cover reduction must be incorporated at the earliest stage of site layout and design to be effective, but outdated development codes in many communities can greatly restrict the scope of impervious cover reduction (see Chapter 2). Finally, the performance and longevity of impervious cover reduction are dependent on the infiltration capability of local soils, the intensity of development, and the future management actions of landowners.

FIGURE 5-6 110th Street, Seattle, part of the Natural Drainage Systems Project. This location exhibits several elements of impervious cover reduction. In particular, vegetated swales were installed and curbs and gutters removed. There are sidewalks on only one side of the street, and they are separated from the road by the swales. The residences' rooftops have been disconnected from the storm-drain systems and are redirected into the swales. SOURCE: Seattle Public Utilities.

Earthwork Minimization

This source control measure seeks to limit the degree of clearing and grading on a development site in order to prevent soil compaction, conserve soils, prevent erosion from steep slopes, and protect zero-order streams. This is accomplished by (1) identifying key soils, drainage features, and slopes to protect and then (2) establishing a limit of disturbance where construction equipment is excluded. This element is an important, but often under-utilized component of local erosion and sediment control plans.

Numerous researchers have documented the impact of mass grading, clearing, and the passage of construction equipment on the compaction of soils, as measured by increase in bulk density, declines in soil permeability, and increases in the runoff coefficient (Lichter and Lindsey, 1994; Legg et al., 1996; Schueler, 2001a,b; Gregory et al., 2006). Another goal of earthwork minimization is to protect zero-order streams, which are channels with defined banks that emanate from a hollow or ravine with convergent contour lines (Gomi et al., 2002). They represent the uppermost definable channels that possess temporary or intermittent flow. Functioning zero-order channels provide major watershed functions, including groundwater recharge and discharge (Schollen et al., 2006; Winter, 2007), important nutrient storage and transformation functions (Bernot and Dodds, 2005; Groffman et al., 2005), storage and retention

of eroded hill-slope sediments (Meyers, 2003), and delivery of leaf inputs and large woody debris. Compared to high-order network streams, zero-order streams are disproportionately disturbed by mass grading, enclosure, or channelization (Gomi et al., 2002; Meyer, 2003).

The practice of earthwork minimization is not widely applied across the country. This is partly due to the limited performance data available to quantify its benefits, and the absence of local or national design guidance or performance benchmarks for the practice.

Erosion and Sediment Control

Erosion and sediment control predates much of the NPDES stormwater permitting program. It consists of the temporary installation and operation of a series of structural and nonstructural practices throughout the entire construction process to minimize soil erosion and prevent off-site delivery of sediment. Because construction is expected to last for a finite and short period of time, the design standards are usually smaller and thus riskier (25-year versus the 100-year storm). By phasing construction, thereby limiting the exposure of bare earth at any one time, the risk to the environment is reduced significantly.

The basic practices include clearing limits, dikes, berms, temporary buffers, protection of drainage-ways, soil stabilization through hydroseeding or mulching, perimeter controls, and various types of sediment traps and basins. All plans have some component that requires filtration of runoff crossing construction areas to prevent sediment from leaving the site. This usually requires a sediment collection system including, but not limited to, conventional settling ponds and advanced sediment collection devices such as polymer-assisted sedimentation and advanced sand filtration. Silt fences are commonly specified to filter distributed flows, and they require maintenance and replacement after storms as shown in Figure 5-7. Filter systems are added to inlets until the streets are paved and the surrounding area has a cover of vegetation (Figure 5-8). Sedimentation basins (Figure 5-9) are constructed to filter out sediments through rock filters, or are equipped with floating skimmers or chemical treatment to settle out pollutants. Other common erosion and sediment control measures include temporary seeding and rock or rigged entrances to construction sites to remove dirt from vehicle tires (see Figure 5-10).

Sediment basins are used to trap sediments and temporarily detain runoff on larger construction sites

FIGURE 5-9 Sediment basin. SOURCE: EPA NPDES Menu of BMPs.

FIGURE 5-10 Rumble strips to remove dirt from vehicle tires. SOURCE: Laura Ehlers.

Control of the runoff's erosive potential is a critical element. Most erosion and sediment control manuals provide design guidance on the capacity and ability of swales to handle runoff without eroding, on the design of flow paths to transport runoff at non-erosive velocities, and on the dissipation of energy at pipe outlets. Examples include rock energy dissipaters, level spreaders (see Figure 5-11), and other devices.

Box 5-3 provides a comprehensive list of recommended construction SCMs. The reader is directed to reviews by Brown and Caraco (1997) and Shaver et al. (2007) for more information. Although erosion and sediment control practices are temporary, they require constant operation and maintenance during the complicated sequence of construction and after major storm events. It is exceptionally important to ensure that practices are frequently inspected and repaired and that sediments are cleaned out. Erosion and sediment control are widely applied in many communities, and most states have some level of design guidance or standards and specifications. Nonetheless, few communities have quantified the effectiveness of a series of construction SCMs applied to an individual site, nor have they clearly defined performance benchmarks for individual practices or their collective effect at the site. In general, there has been little monitoring in the past few decades to characterize the performance of construction SCMs, although a few notable studies have been recently published (e.g., Line and White, 2007). Box 5-4 describes the effectiveness of filter fences and filter fences plus grass buffers to reduce sediment loadings from construction activities and the resulting biological impacts.

BOX 5-3

Recommended Construction Stormwater Control Measures

1. As the top priority, emphasize construction management SCMs as follows:
 - Maintain existing vegetation cover, if it exists, as long as possible.
 - Perform ground-disturbing work in the season with smaller risk of erosion, and work off disturbed ground in the higher risk season.
 - Limit ground disturbance to the amount that can be effectively controlled in the event of rain.
 - Use natural depressions and planning excavation to drain runoff internally and isolate areas of potential sediment and other pollutant generation from draining off the site, so long as safe in large storms.
 - Schedule and coordinate rough grading, finish grading, and erosion control application to be completed in the shortest possible time overall and with the shortest possible lag between these work activities.
2. Stabilize with cover appropriate to site conditions, season, and future work plans. For example:
 - Rapidly stabilize disturbed areas that could drain off the site, and that will not be worked again, with permanent vegetation supplemented with highly effective temporary erosion controls until achievement of at least 90 percent vegetative soil cover.
 - Rapidly stabilize disturbed areas that could drain off the site, and that will not be worked again for more than three days, with highly effective temporary erosion controls.
 - If at least 0.1 inch of rain is predicted with a probability of 40 percent or more, before rain falls stabilize or isolate disturbed areas that could drain off the site, and that are being actively worked or will be within three days, with measures that will prevent or minimize transport of sediment off the property.
3. As backup for cases where all of the above measures are used to the maximum extent possible but sediments still could be released from the site, consider the need for sediment collection systems including, but not limited to, conventional settling ponds and advanced sediment collection devices such as polymer-assisted sedimentation and advanced sand filtration.
4. Specify emergency stabilization and/or runoff collection (e.g., using temporary depressions) procedures for areas of active work when rain is forecast.
5. If runoff can enter storm drains, use a perimeter control strategy as backup where some soil exposure will still occur, even with the best possible erosion control (above measures) or when there is discharge to a sensitive waterbody.
6. Specify flow control SCMs to prevent or minimize to the extent possible:
 - Flow of relatively clean off-site water over bare soil or potentially contaminated areas;
 - Flow of relatively clean intercepted groundwater over bare soil or potentially contaminated areas;
 - High velocities of flow over relatively steep and/or long slopes, in excess of what erosion control coverings can withstand; and
 - Erosion of channels by concentrated flows, by using channel lining, velocity control, or both.
7. Specify stabilization of construction entrance and exit areas, provision of a nearby tire and chassis wash for dirty vehicles leaving the site with a wash water sediment trap, and a sweeping plan.
8. Specify construction road stabilization.
9. Specify wind erosion control.
10. Prevent contact between rainfall or runoff and potentially polluting construction materials, processes, wastes, and vehicle and equipment fluids by such measures as enclosures, covers, and containments, as well as berming to direct runoff.

BOX 5-4

Receiving Water Impacts Associated with Construction Site Discharges

The following is a summary of a recent research project that investigated in-stream biological conditions downstream of construction sites having varying levels of erosion controls (none, the use of filter fences, and filter fences plus grass buffers) for comparison. The project title is *Studies to Evaluate the Effectiveness of Current BMPs in Controlling Stormwater Discharges from Small Construction Sites* and was conducted for the Alabama Water Resources Research Institute, Project 2001AL4121B, by Drs. Robert Angus, Ken Marion, and Melinda Lalor of the University of Alabama at Birmingham. The initial phase of the project, described below, was completed in 2002. While this case study is felt to be representative of many sites across the United States, there are other examples of where silt fences have been observed to be more effective (e.g., Barrett et al., 1998).

Methods

This study was conducted in the upper Cahaba River watershed in north central Alabama, near Birmingham. The study areas had the following characteristics. (1) Topography and soil types representative of the upland physiographic regions in the Southeast (i.e., southern Appalachian and foothill areas); thus, findings from this study should be relevant to a large portion of the Southeast. (2) The rainfall amounts and intensities in this region are representative of many areas of the Southeast and (3) the expanding suburbs of the Birmingham metropolitan area are rapidly encroaching upon the upper Cahaba River and its tributaries. Stormwater runoff samples were manually collected from sheet flows above silt fences, and from points below the fence within the vegetated buffer. Water was sampled during "intense" (≥ 1 inch/hour) rain events. The runoff samples were analyzed for turbidity, particle size distribution (using a Coulter Counter Multi-Sizer IIe), and total solids (dissolved solids plus suspended/non-filterable solids). Sampling was only carried out on sites with properly installed and well-maintained silt fences, located immediately upgrate from areas with good vegetative cover.

Six tributary or upper mainstream sites were studied to investigate the effects of sedimentation from construction sites on both habitat quality and the biological "health" of the aquatic ecosystem (using benthic macroinvertebrates and fish). EPA's Revision to Rapid Bioassessment Protocols for Use in Streams and Rivers was used to assess the habitat quality at the study sites. Each site was assessed in the spring to evaluate immediate effects of the sediment, and again during the following late summer or early fall to evaluate delayed effects.

Results

Effectiveness of Silt Fences. Silt fences were found to be better than no control measures at all, but not substantially. The mean counts of small particles ($< 5 \mu\text{m}$) below the silt fences were about 50 percent less than that from areas with no erosion control measures, even though the fences appeared to be properly installed and in good order. However, the variabilities were large and the difference between the means was not statistically significant. For every variable measured, the mean values of samples taken below silt fences were significantly higher ($p < 0.001$) than samples collected from undisturbed vegetated control sites collected nearby and at the same time. These data therefore indicate that silt fences are only marginally effective at reducing soil particulates in runoff water.

Effectiveness of Filter Fences with Vegetated Buffers. Runoff samples were also collected immediately below filter fences, and below filter fences after flow over buffers having 5, 10, and 15 feet of dense (intact) vegetation. Mean total solids in samples collected below silt fences and a 15-foot-wide vegetated buffer zone were about 20 percent lower, on average, than those samples collected only below the silt fence. The installation of filter fences above an intact, good vegetated buffer removes sediment from construction site runoff more effectively than with the use of filter fences alone.

BOX 5-4 Continued

Biological Metrics Sensitive to Sedimentation Effects (Fish). Analysis of the fish biota indicates that various metrics used to evaluate the biological integrity of the fish community also are affected by highly sedimented streams. As shown in Figure 5-12, the overall composition of the population, as quantified by the Index of Biotic Integrity (IBI) is lower; the proportion and biomass of darters, a disturbance-sensitive group, is lower; the proportion and biomass of sunfish is higher; the Shannon-Weiner diversity index is lower; and the number of disturbance-tolerant species is higher as mean sediment depth increases.

FIGURE 5-12 Association between two fish metrics and amount of stream sediment. NOTE: The IBI is based on numerous characteristics of the fish population. The percent relative abundance of darters is the percentage of darters to all the fish collected at a site. SOURCE: Alabama WRRI.

Benthic Macroinvertebrates. A number of stream benthic macroinvertebrate community characteristics were also found to be sensitive to sedimentation. Metrics based on these characteristics differ greatly between sediment-impacted and control sites (Figure 5-13). Some of the metrics that appear to reflect sediment-associated stresses include the Hilsenhoff Biotic Index (HBI), a variation of the EPT index (percent EPT minus Baetis), and the Sorensen Index of Similarity to a reference site. The HBI is a weighted mean tolerance value; high HBI values indicate sites dominated by disturbance-tolerant macroinvertebrate taxa. The EPT% index is the percent of the collection represented by organisms in the generally disturbance-sensitive orders *Ephemeroptera*, *Plecoptera*, and *Trichoptera*. Specimens of the genus *Baetis* were not included in the index as they are relatively disturbance-tolerant. The HBI and the EPT indices also show positive correlations to several other measures of disturbance, such as percent of the watershed altered by development.

FIGURE 5-13 Associations between two macroinvertebrate metrics and the amount of stream sediment. SOURCE: Alabama WRRI.

Reforestation and Soil Compost Amendments

This set of practices seeks to improve the quality of native vegetation and soils present at the site. Depending on the ecoregion, this may involve forest, prairie, or chaparral plantings, tilling, and amending compacted soils to improve their hydrologic properties.

The goal is to maintain as much predevelopment hydrologic function at a development site as possible by retaining canopy interception, duff/soil layer interception, evapotranspiration, and surface infiltration. The basic methods to implement this practice are described in Cappiella et al. (2006), Pitt et al. (2005), Chollak and Rosenfeld (1998), and Balusek (2003).

At this time, there are few monitoring data to assess the degree to which land reforestation or soil amendments can improve the quality of stormwater runoff at a particular development site, apart from the presumptive watershed research that has shown that forests with undisturbed soils have very low rates of surface runoff and extremely low levels of pollutants in runoff (Singer and Rust, 1975; Johnson et al., 2000; Chang, 2006). More data are needed on the hydrologic properties of urban forests and soils whose ecological functions are stressed or degraded by the urbanization process (Pouyat et al., 1995, 2007).

Pollution Prevention SCMs for Stormwater Hotspots

Certain classes of municipal and industrial operations are required to maintain a series of pollution prevention practices to prevent or minimize contact of pollutants with rainfall and runoff. Pollution prevention practices involve a wide range of operational practices at a site related to vehicle repairs, fueling, washing and storage, loading and unloading areas, outdoor storage of materials, spill prevention and response, building repair and maintenance, landscape and turf management, and other activities that can introduce pollutants into the stormwater system (CWP, 2005). Training of personnel at the affected area is needed to ensure that industrial and municipal managers and employees understand and implement the correct stormwater pollution prevention practices needed for their site or operation.

Examples of municipal operations that may need pollution prevention plans include public works yards, landfills, wastewater treatment plants, recycling and solid waste transfer stations, maintenance depots, school bus and fleet storage and maintenance areas, public golf courses, and ongoing highway maintenance operations. The major industrial categories that require stormwater pollution prevention plans were described in Table 2-3. Both industrial and municipal operations must develop a detailed stormwater pollution prevention plan, train employees, and submit reports to regulators. Compliance has been a significant issue with this program in the past, particularly for small businesses (Duke and Augustenberg, 2006; Cross and Duke, 2008). Recently filed investigations of stormwater hotspots indicate many of these operations are not fully implementing their stormwater pollution prevention plans, and a recent GAO report (2007) indicates that state inspections and enforcement actions are extremely rare.

The goal of pollution prevention is to prevent contact of rainfall or stormwater runoff with pollutants, and it is an important element of the post-construction stormwater plan. However, with the exception of a few industries such as auto salvage yards (Swamikannu, 1994), basic research is lacking on how much greater event mean concentrations are at municipal and industrial stormwater hotspots compared to other urban land uses. In addition, little is presently

known about whether aggressive implementation of stormwater pollution prevention plans actually can reduce stormwater pollutant concentrations at hot spots.

Runoff Volume Reduction—Rainwater Harvesting

A primary goal of stormwater management is to reduce the volume of runoff from impervious surfaces. There are several classes of SCMs that can achieve this goal, including rainwater harvesting systems, vegetated SCMs that evapotranspire part of the volume, and infiltration SCMs. For all of these measures, the amount of runoff volume to be captured depends on watershed goals, site conditions including climate, upstream nonstructural practices employed, and whether the chosen SCM is the sole management measure or part of a treatment train. Generally, runoff-volume-reduction SCMs are designed to handle at least the first flush from impervious surfaces (1 inch of rainfall). In Pennsylvania, control of the 24-hour, two-year storm volume (about 8 cm) is considered the standard necessary to protect stream-channel geomorphology, while base flow recharge and the first flush can be addressed by capturing a much smaller volume of rain (1–3 cm). Where both goals must be met, the designer is permitted to either oversize the volume reduction device to control the larger volume, or build a smaller device and use it in series with an extended detention basin to protect the stream geomorphology (PaDEP, 2006). Some designers have reported that in areas with medium to lower percentage impervious surfaces they are able to control up to the 100-year storm by enlarging runoff-volume-reduction SCMs and using the entire site. In retrofit situations, capture amounts as small as 1 cm are a distinct improvement. It should be noted that there are important, although indirect, water quality benefits of all runoff-volume-reduction SCMs—(1) the reduction in runoff will reduce streambank erosion downstream and the concomitant increases in sediment load, and (2) volume reductions lead to pollutant load reductions, even if pollutant concentrations in stormwater are not decreased.

Rainwater harvesting systems refer to use of captured runoff from roof tops in rain barrels, tanks, or cisterns (Figures 5-14 and 5-15). This SCM treats runoff as a resource and is one of the few SCMs that can provide a tangible economic benefit through the reduction of treated water usage. Rainwater harvesting systems have substantial potential as retrofits via the use of rain barrels or cisterns that can replace lawn or garden sprinkling systems. Use of this SCM to provide gray water within buildings (e.g., for toilet flushing) is considerably more complicated due to the need to construct new plumbing and obtain the necessary permits.

The greatest challenge with these systems is the need to use the stored water and avoid full tanks, since these cannot be responsive in the event of a storm. That is, these SCMs are effective only if the captured runoff can be regularly used for some grey water usage, like car washing, toilet flushing, or irrigation systems (golf courses, landscaping, nurseries). In some areas it might be possible to use the water for drinking, showering, or washing, but treatment to potable water quality would be required. Sizing of the required storage is dependent on the climate patterns, the amount of impervious cover, and the frequency of water use. Areas with frequent rainfall events require less storage as long as the water is used regularly, while areas with cold weather will not be able to utilize the systems for irrigation in the winter and thus require larger storage.

FIGURE 5-14 Rainwater harvesting tanks at a Starbucks in Austin, Texas. SOURCE: Laura Ehlers.

FIGURE 5-15 A Schematic of rainwater harvesting . SOURCE: PaDEP (2006).

One substantial advantage of these systems is their ability to reduce water costs for the user and the ability to share needs. An example of this interaction is the Pelican Hill development in Irvine, California, where excess runoff from the streets and houses is collected in enormous cisterns and used for watering of a nearby golf course. Furthermore, compared to other SCMs, the construction of rainwater harvesting facilities provide a long-term benefit with minimal maintenance cost, although they do require an upfront investment for piping and storage tanks.

Coombes et al. (2000) found that rainwater harvesting achieved a 60 to 90 percent reduction in runoff volume; in general, few studies have been conducted to determine the performance of these SCMs. It should be noted that rainwater harvesting systems do collect airborne deposition and acid rain.

Runoff Volume Reduction—Vegetated

A large and very promising class of SCMs includes those that use infiltration and evapotranspiration via vegetation to reduce the volume of runoff. These SCMs also directly address water quality of both surface water and groundwater by reducing streambank erosion, capturing suspended solids, and removing other pollutants from stormwater during filtration through the soil (although the extent to which pollutants are removed depends on the specific pollutant and the local soil chemistry). Depending on their design, these SCMs can also reduce peak flows and recharge groundwater (if they infiltrate). These SCMs can often be added as retrofits to developed areas by installing them into existing lawns, rights of way, or traffic islands. They can add beauty and property value.

Flow volume is addressed by this SCM group by first capturing runoff, creating a temporary holding area, and then removing the stored volume through infiltration and evapotranspiration. Examples include bioswales, bioretention, rain gardens, green roofs, and bioinfiltration. Swales refer to grassy areas on the side of the road that convey drainage. These were first designed to move runoff away from paved areas, but can now be designed to achieve a certain contact time with runoff so as to promote infiltration and pollutant removal (see Figure 5-

16). Bioretention generally refers to a constructed sand filter with soil and vegetation growing on top to which stormwater runoff from impervious surfaces is directed (Figure 5-17). The original rain garden or bioretention facilities were constructed with a fabric at the bottom of the prepared soil to prevent infiltration and instead had a low-level outflow at the bottom. Green roofs (Figure 5-18) are very similar to bioretention SCMs. They tend to be populated with a light expanded shale-type soil and succulent plants chosen to survive wet and dry periods. Finally, bioinfiltration is similar to bioretention but is better engineered to achieve greater infiltration (Figure 5-19). All of these devices are usually at the upper end of a treatment train and designed for smaller storms, which minimizes their footprint and allows for incorporation within existing infrastructure (such as traffic control devices and median strips). This allows for distributed treatment of the smaller volumes and distributed volume reduction.

SOURCE: Robert Traver.

These SCMs work by capturing water in a vegetated area, which then infiltrates into the soil below. They are primarily designed to use plant material and soil to evapotranspire the runoff over several days. A shallow depth of ponding is required, since the inflows may exceed the possible infiltration ability of the native soil. This ponding is maintained above an engineered sandy soil mixture and is a surface-controlled process (Hillel, 1998). Early in the storm, the soil moisture potential creates a suction process that helps draw water into the SCM. This then changes to a steady rate that is “practically equal to the saturated hydraulic conductivity” of the subsurface (Hillel, 1998). The hydrologic design goal should be to maximize the volume of water that can be held in the soil, which necessitates consideration of the soil hydraulic conductivity (which varies with temperature), climate, depth to groundwater, and time to drain. Usually these devices are designed to empty between 24 and 72 hours after a storm event. In some cases (usually bioretention), these SCMs have an underdrain.

The choice of vegetation is an important part of the design of these SCMs. Many sites where infiltration is desirable have highly sandy soils, and the vegetation has to be able to endure both wet and dry periods. Long root growths are desired to promote infiltration (Barr Engineering Co., 2001), and plants that attract birds can reduce the insect population. Bioretention cells may be wet for longer periods than bioinfiltration sites, requiring different plants. Denser plantings or “thorns” may be needed to avoid the destruction caused by humans and animals taking shortcuts through the beds.

The pollutant removal mechanism operating for volume-reduction SCMs are different for each pollutant type, soil type, and volume-reduction mechanism. For bioretention and SCMs using infiltration, the sedimentation and filtration of suspended solids in the top layers of the soil are extremely efficient. Several studies have shown that the upper layers of the soil capture metals, particulate nutrients, and carbon (Pitt, 1996; Deschesne et al., 2005; Davis et al., 2008). The removal of dissolved nutrients from stormwater is not as straightforward. While ammonia is caught by the top organic layer, nitrate is mobile in the soil column. Some bioretention systems have been built to hold water in the soil for longer periods in order to create anaerobic conditions that would promote denitrification (Hunt and Lord, 2006a). Phosphorus removal is related to the amount of phosphorus in the original soil. Some studies have shown that bioretention cells built with agricultural soils increased the amount of phosphorus released. Chlorides pass through the system unchecked (Ermilio and Traver, 2006), while oils and greases are easily removed by the

organic layer. Hunt et al. (2008) have reported in studies in North Carolina that the drying cycle appears to kill off bacteria. Temperature is not usually a concern as most storms do not overflow these devices. Green roofs collect airborne deposition and acid rain and may export nutrients when they overflow. However, this must be tempered by the fact that in larger storms, most natural lands would produce nutrients.

A group of new research studies from North America and Australia have demonstrated the value of many of these runoff-volume-reduction practices to replicate predevelopment hydrology at the site. The results from 11 recent studies are given in Table 5-3, which shows the runoff reduction capability of bioretention. As can be seen, the reduction in runoff volume achieved by these practices is impressive—ranging from 20 to 99 percent with a median reduction of about 75 percent. Box 5-5 discusses the excellent performance of the bioswales installed during Seattle’s natural drainage systems project (see also Horner et al., 2003; Jefferies, 2004; Stagge, 2006). Bioinfiltration has been less studied, but one field study concluded that close to 30 percent of the storm volume was able to be removed by bioinfiltration (Sharkey, 2006). A very recent case study of bioinfiltration is provided in Box 5-6, which demonstrates that the capture of small storms through these SCMs is extremely effective in areas where the majority of the rainfall falls in smaller storms.

	MD	52 to 65%	Davis et al. (2008)

**BOX 5-5
 Bioswale Case Study
 100th Street Cascade, Seattle, Washington**

A recent example of the ability of SCMs to accomplish a variety of goals was illustrated for water quality swales in Seattle, Washington. As part of its Natural Drainage Systems Project, the City of Seattle retrofitted several blocks of an urban residential neighborhood with curbside vegetated swales. On NW 110th Street, the two-block-long system was developed as a cascade, due to the steep slope (6 percent). Twelve stepped, in-series biofilters were installed between properties and the road, each of which contains a storage area and an overflow weir. During rain events, the cells were designed to fill before emptying into the cell downstream. The soils in the bottom of each cell were over one foot thick and consisted of river rocks overlain by a swale mix. Native plants were chosen to vegetate the sides of the swale.

Extensive flow and water quality sampling occurred during 2003–2006 at the inflow and outflow of the biofilters as well as at reference points elsewhere in the neighborhood that are not served by the new SCMs. Perhaps the most profound observation was that almost 50 percent of all rainfall flowing into the cascade was infiltrated, resulting in a corresponding reduction in runoff. Indeed, the cascade discharged measurable flow only during 49 of 235 storm events during the period. Depending on preceding conditions, the cascade was able to retain all of the flow for storms up to 1 inch in magnitude. In addition to the reduction in runoff affected by the swales, they also achieved significant peak flow reduction, as shown in Figure 5-20. Many peak flow rates were entirely dampened, even those where the inflow peak rate was as high as 0.7 cfs.

FIGURE 5-20 Peak flow rates at the inlet and outlet of the cascade, as measured by two different devices: Campbell Scientific (left) and ISCO (right). SOURCE: Horner and Chapman (2007).

continues next page

BOX 5-5 Continued

Water quality data were also extremely encouraging, as shown in Table 5-4. For total suspended solids, influent concentration of 94 mg/L decreased to 29 mg/L at the outlet of the cascade. Similar percent removals were observed for total copper, total phosphorus, total zinc, and total lead (see Table 5-4). Soluble phosphorus concentrations tended to increase from the inflow of the cascade to the outflow.

TABLE 5-4 Typical Outflow Quality from the 100th Street Cascade. Permission pending.

Pollutant	Range (mg/L)
Total Suspended Solids	10–40
Total Nitrogen	0.6–1.4
Total Phosphorus	0.09–0.23
Soluble Reactive Phosphorus	0.02–0.05
Total Copper	0.004–0.008
Dissolved Copper	0.002–0.005
Total Zinc	0.04–0.11
Dissolved Zinc	0.02–0.06
Total Lead	0.002–0.007
Dissolved Lead	<0.001
Motor Oil	0.11–0.33

SOURCE: Horner and Chapman (2007).

Taking both measured concentrations and volume reduction into account, the cascade reduced the mass loadings for the contaminants by 60 percent to greater than 90 percent. As shown in Table 5-5, pollutants associated with sediments were reduced to the greatest extent, while dissolved pollutants were less readily removed.

TABLE 5-5 Pollutant Mass Loading Reductions at 100th Street Cascade. Permission pending.

Pollutant	Percent Reduction (90% Confidence Interval)
Total Suspended Solids	84 (72–92)
Total Nitrogen	63 (53–74)
Total Phosphorus	63 (49–74)
Total Copper	83 (77–88)
Dissolved Copper	67 (50–78)
Total Zinc	76 (46–85)
Dissolved Zinc	55 (21–70)
Total Lead	90 (84–94)
Motor Oil	92 (86–97)

SOURCE: Horner and Chapman (2007).

This level of performance was compared to other parts of the neighborhood treated with conventional ditch and pipe systems. The concentrations of almost all pollutants at the outlet of the 100th Cascade was significantly lower than a corresponding outlet at 120th Street. Furthermore, the ability of this SCM to attenuate peak flows and reduce runoff was remarkable.

BOX 5-6
SCM Evaluation Through Monitoring:
Villanova Bioinfiltration SCM

The Bioinfiltration Traffic Island located on the campus of Villanova University in Southeastern Pennsylvania is part of the Villanova Urban Stormwater Partnership (VUSP) BMP Demonstration Park (see Figure 5-21). Originally funded through the Pennsylvania Growing Greener Program, and now through the State's 319 nonpoint source monitoring program, the site has been monitored continuously since soon after it was constructed in 2001. This monitoring has led to a wealth of information about the performance and monitoring needs of infiltration SCMs.

FIGURE 5-21 Villanova Bioinfiltration Traffic Island SCM. SOURCE : Reprinted, with permission, from VUSP. Copyright by Villanova Urban Stormwater Partnership.

The SCM is a retrofit of an existing curb-enclosed traffic island in the parking lot of a university dormitory complex. The original grass area was dug out to approximately six feet. The soil removed during the excavation was then mixed with sand onsite to create a 50 percent sand-soil mixture. This soil mixture was then placed back into the excavation to a depth of approximately four feet, leaving a surface depression that is an average of two feet deep. Care was taken during construction to prevent any compaction of either the soil mixture or the undisturbed soil below. Placement of the mixed soil is shown in Figure 5-22.

During construction two curb cuts were created to direct runoff into the SCM. Creation of one of the cuts entailed filling and paving over an existing stormwater inlet to redirect the runoff that previously entered the stormwater drainage system of the parking lot. Another existing inlet was used to collect and redirect runoff into the SCM. Plants were chosen based on their ability to thrive in both extreme wet and dry conditions; the species chosen are commonly found on sand dunes where similar wet/dry conditions may exist.

The contributing watershed is approximately 50,000 square feet and is 52 percent impervious surfaces. The design goal of the SCM was for it to temporarily store the first inch of runoff. The one-inch capture depth is based on an analysis of local historical rainfall data showing that capture of the first inch of each storm would account for approximately 96 percent of the annual rainfall. This capture depth would therefore also account for the majority of the annual pollutant load coming from the drainage area.

BOX 5-6 Continued

Continuous monitoring over multiple years has increased our understanding of how this type of structure operates and its benefits. For example, Heasom et al. (2006) was able to produce a continuous hydrologic flow model of the site based on season. Figure 5-23 shows the variability of the infiltration rate on a seasonal basis, and the relationship between infiltration and temperature (Emerson and Traver, 2008). This work has also shown no statistical change in performance over the five-year monitoring period.

FIGURE 5-23 Seasonal Infiltration Rate. SOURCE: Reprinted, with permission, from Emerson and Traver (2008). Copyright 2008 by Journal of Irrigation and Drainage Engineering.

When examining the yearly performance of the site from a surface water standpoint, it is easily shown that on a regular basis approximately 50 to 60 percent of the runoff that reaches the site is removed from the surface waters, and 80 to 85 percent of the rainfall is infiltrated (Figure 5-24).

FIGURE 5-24 2003 Performance and 2006 Performance. SOURCE: Reprinted, with permission, from VUSP. Copyright by Villanova Urban Stormwater Partnership.

The performance of the SCM during individual storm events was examined in 2005. Out of 77 rainfall events, overflow was recorded for only seven events. Generally overflow did not occur for rainfalls less than 1.95 inches except for one occasion. As the bowl volume is much less than this value, substantial infiltration must be occurring during the storm event. When one extreme 6-inch storm was recorded (Figure 5-25), it was surprising to note that infiltration occurred all during the storm event, as did some unexpected peak flow reduction. What is even more impressive is to examine the reduction in the duration of flows, which is directly related to downstream channel erosion (Figure 5-26). Clearly the bioinfiltration SCM exceeded its design goals.

FIGURE 5-25 October 2005 extreme storm event. SOURCE: Reprinted, with permission, from VUSP. Copyright by Villanova Urban Stormwater Partnership.

FIGURE 5-26 Flow duration curves, October 2005. SOURCE: Reprinted, with permission, from VUSP. Copyright by Villanova Urban Stormwater Partnership.

Research on this site is currently examining water quality benefits and groundwater interactions. When evaluating the pollutant removal of bioinfiltration, it is critical to consider flow volumes and pollutant levels together. For example, during many of the overflow events, there were higher nutrient levels leaving the SCM than entering due to the plants contained within the SCM. However, when the runoff volume reduction is considered, the total nitrogen and phosphorus removed from the influent is impressive (Davis et al., 2008). Water quality studies of the infiltrated water are still incomplete but generally show some conversion of nitrate to nitrite, and high chlorides from snow melt chemicals moving through the system. Nutrient levels are relatively low in the samples at the 8-foot depth.

The strengths of vegetated runoff-volume-reduction SCMs include the flexibility to utilize the drainage system as part of the treatment train. For example, bioswales can replace drainage pipes, green roofs can be installed on buildings, and bioretention can replace parking borders (Figure 5-27), thereby reducing the footprint of the stormwater system. Also, through the use of swales and reducing pipes and inlets, costs can be offset. Vegetated systems are more tolerant of the TSS collected, and their growth cycle maintains pathways for infiltration and prevents clogging. Freeze-thaw cycles also contribute to pathway maintenance. The aesthetic appeal of vegetated SCMs is also a significant strength.

Weaknesses include the dependence of these SCMs on native soil infiltration and the need to understand groundwater levels and karst geology, particularly for those SCMs designed to infiltrate. For bioinfiltration and bioretention, most failures occur early on and are caused by sedimentation and construction errors that reduce infiltration capacity, such as stripping off the topsoil and compacting the subsurface. Once a good grass cover is established in the contributing area, the danger of sedimentation is reduced. Nonetheless, the need to prevent sediment from overwhelming these structures is critical. The longevity of these SCMs and their vulnerability to toxic spills are a concern (Emerson and Traver, 2008), as is their failure to reduce chlorides. Finally, in areas where the land use is a hot spot, or where the SCM could potentially contaminate the groundwater supply, bioretention, non-infiltrating bioswales, and green roofs may be more suitable than infiltration SCMs.

The role of infiltration SCMs in promoting groundwater recharge deserves additional consideration. Although this is a benefit of infiltration SCMs in regions where groundwater levels are dropping, it may be undesirable in a few limited scenarios. For example, in the arid southwest contributions to base flow from irrigation have turned some dry ephemeral stream systems into perennial streams that support the growth of dense vegetation, which may be less desirable habitat for certain riparian species (like the Arroyo toad in Southern California). Infiltration SCMs could contribute to changing the flow regime in cases such as these. In most urban areas, there is so much impervious cover that it would be difficult to “overinfiltrate.” Nonetheless, the use of infiltration SCMs will change local subsurface hydrology, and the ramifications of this—good and bad—should be considered prior to their installation.

FIGURE 5-27 North Carolina Retrofit Bioretention SCMs. SOURCE: Traver.

Maintenance of vegetated runoff-volume-reduction SCMs is relatively simple. A visit after a rainstorm to check for plant health, to check sediment buildup, and to see if the water is ponded can answer many questions. Maintenance includes trash pickup and seasonal removal of dead grasses and weeds. Sediment removal from pretreatment devices is required. Depending on the pollutant concentrations in the influent, the upper layer of organic matter may need to be removed infrequently to maintain infiltration and to prevent metal and nutrient buildup.

At the site level, the chief factors that lead to uncertainty are the infiltration performance of the soil, particular for the limiting subsoil layer, and how to predict the extent of pollutant removal. Traditional percolation tests are not effective to estimate the infiltration performance; rather, testing hydraulic conductivity is required. Furthermore, the infiltration rate varies depending on temperature and season (Emerson and Traver, 2008). Basing measurements on percent removal of pollutants is extremely misleading, since every site and storm generates different levels of pollutants. The extent of pollutant removal depends on land use, time between storms, seasons, and so forth. These factors should be part of the design philosophy for the site. Finally, it should also be pointed out that climate is a factor determining the effectiveness of some of these SCMs. For example, green roofs are more likely to succeed in areas having smaller, more frequent storms (like the Pacific Northwest) compared to areas subjected to less frequent, more intense storms (like Texas).

Runoff Volume Reduction—Subsurface

Infiltration is the primary runoff-volume-reduction mechanism for subsurface SCMs, such that much of the previous discussion is relevant here. Thus, like vegetated SCMs, these SCMs provide benefits for groundwater recharge, water quality, stream channel protection, peak flow reduction, capture of the suspended solids load, and filtration through the soil (Ferguson, 2002). Because these systems can be built in conjunction with paved surfaces (i.e., they are often buried under parking lots), the amount of water captured, and thus stream protection, may be higher than for vegetated systems. They also have lower land requirements than vegetated systems, which can be an enormous advantage when using these SCMs during retrofitting, as long as the soil is conducive to infiltration.

Similar to vegetated SCMs, this SCM group works primarily by first capturing runoff and then removing the stored volume through infiltration. The temporary holding area is made either of stone or using manufactured vaults. Examples include pervious pavement, infiltration trenches, and seepage pits (see Figures 5-28, 5-29, 5-30, 5-31, and 5-32). As with vegetated SCMs, a shallow depth of ponding is required, since the inflows may exceed the possible infiltration ability of the native soil. In this case, the ponding is maintained within a rock bed under a porous pavement or in an infiltration trench. These devices are usually designed to empty between 24 and 72 hours after the storm event.

The infiltration processes operating for these subsurface SCMs are similar to those for the vegetated devices previously discussed. Thus, much like for vegetated systems, the level of control achieved depends on the infiltration ability of the native soils, the percent of impervious surface area in the contributing watershed, land use contributing to the pollutant loadings, and climate. A large number of recent studies have found that permeable pavement can reduce runoff volume by anywhere from 50 percent (Rushton, 2002; Jefferies, 2004; Bean et al., 2007)

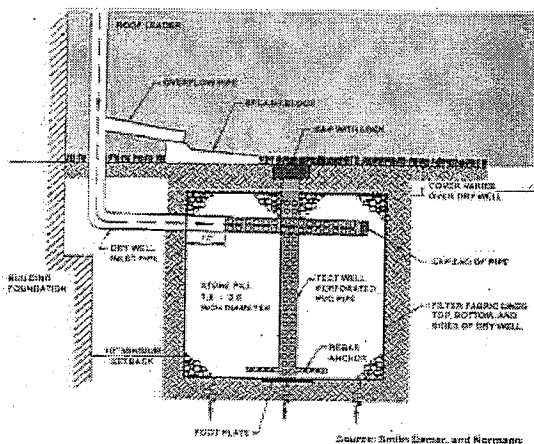

FIGURE 5-28 Schematic of a seepage pit. PaDEP.

FIGURE 5-31 Pervious concrete at Villanova University. SOURCE: Reprinted, with permission from VUSP. Copyright by VUSP.

FIGURE 5-32 A small office building conversion at the edge of downtown Denver included the replacement of a portion of the site's parking with modular block porous pavement underlain by an 18-inch layer of crushed rock. Rainfall on the porous pavement and roof runoff for most storm events are contained in the reservoir created by the crushed rock. The pavement infiltrates runoff from most storm events for one-third of the impervious area on the half-acre site.

to as much as 95 percent or greater (van Seters et al., 2006; Kwiatkowski et al., 2007). Box 5-7 describes the success of a recent retrofitting of asphalt with pervious pavement at Villanova University.

The strengths of subsurface runoff-volume-reduction SCMs are similar to those of their vegetated counterparts. Additional attributes include their ability to be installed under parking areas and to manage larger volumes of rainfall. These SCMs typically have few problems with safety or vector-borne diseases because of their subsurface location and storage capacity, and they can be very aesthetically pleasing. The potential of permeable pavement could be particularly far-reaching if one considers the amount of impervious surface in urban areas that is comprised of roads, driveways, and parking lots.

The weaknesses of these SCMs are also similar to those of vegetated systems, including their dependence on native soil infiltration and the need to understand groundwater levels and karst geology. Simply estimating the soil hydraulic conductivity can have an error rate of an order of magnitude. Specifically for subsurface systems that use geotextiles (not permeable pavement), there is a danger of TSS being compressed against the bottom of the geotextile, preventing infiltration. There are no freeze-thaw cycles or vegetated processes that can reopen pathways, so the control of TSS is even more critical to their life span. In most cases (permeable pavement is an exception), pretreatment is required, except for the cleanest of sources (like a slate roof). Typically, manufactured devices, sediment forebays, or grass strips are part of the design of subsurface SCMs to capture the larger sediment particles.

The maintenance of subsurface runoff-volume-reduction SCMs is relatively simple but critical. If inspection wells are installed, a visit after a rainstorm will check that the volume is captured, and later that it has infiltrated. Porous surfaces should undergo periodic vacuum street sweeping when a sediment source is present. Pretreatment devices require sediment removal. The difficulty with this class of SCMs is that, if a toxic spill occurs or maintenance is not proactive, there are no easy corrective measures other than replacement.

Low-Impact Development. LID refers primarily to the use of small, engineered, on-site stormwater practices to treat the quality and quantity of runoff at its source. It is discussed here because the SCMs that are thought of as LID—particularly vegetated swales, green roofs, permeable pavement, and rain gardens—are all runoff-volume-reduction SCMs. They are designed to capture the first portion of a rainfall event and to treat the runoff from a few hundred square meters of impervious cover.

As discussed earlier, several studies have measured the runoff volume reduction of individual LID practices. Fewer studies are available on whether multiple LID practices, when used together, have a cumulative benefit at the neighborhood or catchment scale. Four monitoring studies have clearly documented a major reduction in runoff from developments that employ LID and Better Site Design (see Box 5-8) compared to those that do not. In addition, six studies have documented the runoff reduction benefits of LID at the catchment or watershed scale using a modeling approach (Alexander and Heaney, 2002; Stephens et al., 2002; Holman-Dodds et al., 2003; Coombes, 2004; Hardy et al., 2004; Huber et al., 2006).

BOX 5-7
Evaluation Through Monitoring: Villanova Pervious Concrete SCM

Villanova University's Stormwater Research and Demonstration Park is home to a pervious concrete infiltration site (Figure 5-33). The site, formerly a standard asphalt paved area, is located between two dormitories. The area was reconstructed in the summer of 2002 and outfitted with three infiltration beds overlain with pervious concrete. Usage of the site consists primarily of pedestrian traffic with some light automobile traffic. The pervious concrete site is designed to infiltrate small-volume storms (1 to 2 inches). Roof top runoff is directly piped to the rock bed under the concrete. For these smaller events, there is essentially no runoff from the site.

Figure 5-33 Villanova University pervious concrete retrofit site. SOURCE: Reprinted, with permission, from VUSP. Copyright by VUSP.

The pervious concrete is outlined with decorative pavers that divide the pervious concrete into three separate sections as seen in Figure 5-33. Underneath these three sections are individual storage beds. Since the site lies on a significant slope it was necessary to create earthen dams that isolate each storage area. At the top of each dam there is an overflow pipe which connects the storage area with the next one downstream. The final storage bed has an overflow that connects to the existing storm sewer. The beds are approximately 4 feet deep and are filled with stone, producing about 40 percent void space within the beds. A geotextile pervious liner was laid down to separate the storage beds from the undisturbed soil below (Figure 5-34). The primary idea was to avoid any upward migration of the in-situ soil, which could possibly reduce the capacity of the beds over time.

FIGURE 5-34 Infiltration bed under construction. Pervious concrete has functionality and workability similar to that of regular concrete. However, the pervious concrete mix lacks the sand and other fine particles found in regular concrete. This creates a significant amount of void space which allows water to flow relatively unobstructed through the concrete. This site was the first attempt at creating a pervious concrete SCM in the area, and there were construction and material problems. Since that time the industry has matured, and a second site on campus constructed in 2007 has not had any significant difficulties. SOURCE: Reprinted, with permission, from VUSP. Copyright by VUSP.

Note the runoff from impervious concrete spilling over to the pervious concrete

Continuous monitoring of the site over a number of years has considerably increased our understanding of infiltration. Similar to the bioinfiltration site (Box 5-6), the infiltration rate of permeable concrete does vary as a function of temperature (Braga et al., 2007; Emerson and Traver, 2008), and the SCM volume reduction is impressive. As shown in Figure 5-35, over 95 percent of the yearly rainfall was infiltrated with minimal overflow. Besides hydrologic plots, water quality plots also show the benefits of permeable concrete (Kwiatkowski et al., 2007). Because over 95 percent of the runoff is infiltrated, well over 95 percent of the pollutant mass is also removed. Figure 5-36 shows the level of copper extracted from lysimeters buried under the rock bed and surrounding grass. The plot is arranged in quartiles, with readings in milligrams per liter. Lysimeter samples from under the surrounding grass and one foot and four feet under the infiltration bed all report almost no copper, compared to samples taken from the port in the rock bed and from the gutters draining the roof tops.

**BOX 5-8
 Jordan Cove—An LID Watershed Project**

LID refers to the use of a system of small, on-site SCMs to counteract increases in flow and pollution following development and to control smaller runoff events. Although some studies are available that measure the runoff volume reduction of individual LID practices, fewer studies are available on whether multiple LID practices, when used together, have a cumulative benefit at the neighborhood or catchment scale. Of those listed in Table 5-6, Jordan Cove is the most extensively studied, as it was monitored for ten years as part of a paired watershed study that included a site with no SCMs and a site with traditional (detention) SCMs. The watersheds were monitored during calibration, construction, and post-construction periods. The project consisted of 12 lots, and the SCMs used were bioretention, porous pavements, no-mow areas, and education for the homeowners (Figure 5-37).

TABLE 5-6 Review of Recent LID Monitoring Research on a Catchment Scale

Location	Practices	Runoff Reduction
Jordan Cove, USA Dietz and Clausen (2008)	Permeable pavers, bioretention, grass swales, education	84%
Somerset Heights, USA Cheng et al. (2005)	Grass swale, bioretention, and rooftop disconnection	45%
Figtree Place, Australia Coombes et al. (2000)	Rain tanks, infiltration trenches, swales	100%

BOX 5-8 Continued

Figure 5-38 (right panel) displays the hydrograph from a post-construction storm comparing the LID, traditional, and control watersheds. Note that the traditional watershed shows the delay and peak reduction from the detention basins, while the LID watershed has almost no runoff. The LID watershed was found to reduce runoff volume by 74 percent by increasing infiltration over preconstruction levels.

FIGURE 5-38. Significant changes in runoff volume (m^3 /week), runoff depth (cm/week) and peak discharge (m^3 /sec/week) after construction was completed (left panel). Hydrograph of all three subdivisions in the project, showing the larger volume and rate of runoff from the traditional and control subdivisions, as compared to the LID (right panel). Permission pending.

Comparisons of nutrient and metal concentrations and total export in the surface water shows the value of the LID approach as well as the significance of the reduction in runoff volume. Figure 5-39 shows the changes in pollutant concentration and mass export before and after construction for the traditional and LID subdivisions. Note that concentrations of TSS and nutrients are increased in the LID subdivision (left-hand panel); this is because swales and natural systems are used in place of piping as a "green" drainage system and because only larger storms leave the site. The right-hand panel shows how the large reduction in runoff achieved through infiltration can dramatically reduce the net export of pollutants from the LID watershed.

FIGURE 5-39 Significant changes in pollutant concentration, after construction was completed (left). Units are mg/L for NO_3 -N, NH_3 -N, TKN, TP, and BOD, and μ g/L for Cu, Pb, and Zn. Significant changes in mass export (kg/ha/year) after construction was completed (right). Permission pending

Peak Flow Reduction and Runoff Treatment

After efforts are made to prevent the generation of pollutants and to reduce the volume of runoff that reaches stormwater systems, stormwater management focuses on the reduction of peak flows and associated treatment of polluted runoff. The main class of SCMs used to accomplish this is extended detention basins, versions of which have dominated stormwater management for decades. These include a wide variety of ponds and wetlands, including wet ponds (also known as retention basins), dry extended detention ponds (as known as detention basins), and constructed wetlands. By holding a volume of stormwater runoff for an extended period of time, extended detention SCMs can achieve both water quality improvement and reduced peak flows. Generally the goal is to hold the flows for 24 hours at a minimum to maximize the opportunity of settling, adsorption, and transformation of pollutants (based on past pollutant removal studies) (Rea and Traver, 2005). For smaller storm events (one- to two-year storms), this added holding time also greatly reduces the outflows from the SCM to a level that the stream channel can handle. Most wet ponds and stormwater wetlands can hold a “water quality” volume, such that the flows leaving in smaller storms have been held and “treated” for multiple days. Extended detention dry ponds greatly reduce the outflow peaks to achieve the required residence times.

Usually extended detention devices are lower in the treatment train of SCMs, if not at the end. This is both due to their function (they are designed for larger events) and because the required water sources and less permeable soils needed for these SCMs are more likely to be found at the lower areas of the site. Some opportunities exist to naturalize dry ponds or to retrofit wet ponds into stormwater wetlands but it depends on their site configuration and hydrology. Stormwater wetlands are shown in Figures 5-40 and 5-41. A wet pond and a dry extended detention basin are shown in Figures 5-42 and 5-43.

Simple ponds are little more than a hole in the ground, in which stormwater is piped in and out. Dry ponds are meant to be dry between storms, whereas wet ponds have a permanent pool throughout the year. Detention basins reduce peak flows by restricting the outflows and creating a storage area. Depending on the detention time, outflows can be reduced to levels that do not accelerate erosion, that protect the stream channel, and that reduce flooding.

FIGURE 5-40 Constructed wetland at
SOURCE: PaDEP (2006).

FIGURE 5-41 Retrofitted stormwater wetland.

VUSP. Copyright by VUSP.

The flow normally enters the structure through a sediment forebay (Figure 5-44), which is included to capture incoming sediment, remove the larger particles through settling, and allow for easier maintenance. Then a meandering path or cell structure is built to “extend” and slow down the flows. The main basin is a large storage area (sometimes over the meandering flow paths). Finally, the runoff exits through an outflow control structure built to retard flow.

Wet ponds, stormwater wetlands, and (to a lesser extent) dry extended detention ponds provide treatment. The first step in treatment is the settling of larger particles in the sediment forebay. Next, for wet ponds a permanent pool of water is maintained so that, for smaller storms, the new flows push out a volume that has had a chance to interact with vegetation and be “treated.” This volume is equivalent to an inch of rain over the impervious surfaces in the drainage area. Thus, what exits the SCM during smaller storm events is baseflow contributions and runoff that entered during previous events. For dry extended detention ponds, there is no permanent pool and the outlet is instead greatly restricted. For all of these devices, vegetation is considered crucial to pollutant removal. Indeed, wet ponds are designed with an aquatic bench around the edges to promote contact with plants. The vegetation aids in reduction of flow velocities, provides growth surfaces for microbes, takes up pollutants, and provides filtering (Braskerud, 2001).

FIGURE 5-42 Wet pond. SOURCE: PaDEP (2006).

FIGURE 5-43 Dry extended detention pond. SOURCE: PaDEP (2006).

The ability of detention structures to achieve a certain level of control is size related—that is, the more peak flow reduction or pollutant removal required, the more volume and surface area are needed in the basin. Because it is not simply the peak flows that are important, but also the duration of the flows that cause damage to the stream channels (McCuen, 1979; Loucks et al., 2005), some detention basins are currently sized and installed in series with runoff-volume-reduction SCMs.

The strength of extended detention devices is the opportunity to create habitats or picturesque settings during stormwater management. The weaknesses of these measures include large land requirements, chloride buildup, possible temperature effects, and the creation of habitat for undesirable species in urban areas. There is a perception that these devices promote mosquitoes, but that has not been found to be a problem when a healthy biological habitat is created (Greenway et al., 2003). Another drawback of this class of SCMs is that they often have limited treatment capacity, in that they can reduce pollutants in stormwater only to a certain level. These so-called irreducible effluent concentrations have been documented mainly for ponds and stormwater wetlands, as well as sand filters and grass channels (Schueler, 1998). Finally, it should be noted that either a larger watershed (10–25 acres; CWP, 2004) or a continuous water source is needed to sustain wet ponds and stormwater wetlands.

Maintenance requirements for extended detention basins and wetlands include the removal of built-up sediment from the sediment forebay, harvesting of grasses to remove accumulated nutrients, and repair of berms and structures after storm events. Inspection items relate to the maintenance of the berm and sediment forebay.

While the basic hydrologic function of extended detention devices is well known, their performance on a watershed basis is not. Because they do not significantly reduce runoff volume and are designed on a site-by-site basis using synthetic storm patterns, their exclusive use as a flood reduction strategy at the watershed scale is uncertain (McCuen, 1979; Traver and Chadderton, 1992). Much of this variability is reduced when they are coupled with volume reduction SCMs at the watershed level. Pollutant removal is effected by climate, short-circuiting, and by the schedule of sediment removal and plant harvesting. Extreme events can resuspend captured sediments, thus reintroducing them into the environment. Although there is debate, it seems likely that plants will need to be harvested to accomplish nutrient removal (Reed et al., 1998).

Runoff Treatment

As mentioned above, many SCMs associated with runoff volume reduction and extended detention provide a water quality benefit. There are also some SCMs that focus primarily on water quality with little peak flow or volume effect. Designed for smaller storms, these are usually based on filtration, hydrodynamic separation, or small-scale bioretention systems that drain to a subsequent receiving water or other device. Thus, often these SCMs are used in conjunction with other devices in a treatment train or as retrofits under parking lots. They can be very effective as pretreatment devices when used “higher up” in the watershed than infiltration structures. Finally, in some cases these SCMs are specifically designed to reduce peak flows in addition to providing water quality benefits by introducing elements that make them similar to detention basins; this is particularly the case for sand filters.

The sand filter is relied on as a treatment technology in many regions, particular those where stream geomorphology is less of a concern and thus peak flow control and runoff volume reduction are not the primary goals. These devices can be effective at removing suspended sediments and can extend the longevity and performance of runoff-volume-reduction SCMs. They are also one of the few urban retrofits available, due to the ability to implement them within traditional culvert systems. Figures 5-45 and 5-46 show designs for the Austin sand filter and the Delaware sand filter.

Filters use sand, peat, or compost to remove particulates, similar to the processes used in drinking water plants. Sand filters primarily remove suspended solids and ammonia nitrogen. Biological material such as peat or compost provides adsorption of contaminants such as dissolved metals, hydrocarbons, and other organic chemicals. Hydrodynamic devices use rotational forces to separate the solids from the flow, allowing the solids to settle out of the flow stream. There is a recent class of bioretention-like manufactured devices that combine inlets with planters. In these systems, small volumes are directed to a soil planter area, with larger flows bypassing and continuing down the storm sewer system. In any event, for manufactured items the user needs to look to the manufacturer's published and reviewed data to understand how the device should be applied.

The level of control that can be achieved with these SCMs depends entirely on sizing of the device based on the incoming flow and pollutant loads. Each unit has a certified removal rate depending on inflow to the SCM. Also all units have a maximum volume or rate of flow they can treat, such that higher flows are bypassed with no treatment. Thus, the user has to determine what size unit is needed and the number to use based on the area's hydrologic cycle and what criteria are to be met.

With the exception of some types of sand filters, the strengths of water quality SCMs are that they can be placed within existing infrastructure or under parking lots, and thus do not take up land that may be used for other purposes. They make excellent choices for retrofit situations. For filters, there is a wealth of experience from the water treatment community on their operations. For all manufactured devices there are several testing protocols that have been set up to validate the performance of the manufactured devices (the sufficiency of which is discussed in Box 5-9). Weaknesses of these devices include their cost and maintenance requirements.

BOX 5-9

Insufficient Testing of Proprietary Stormwater Control Measures

Manufacturers of proprietary SCMs offer a service that can save municipalities time and money. Time is saved by the ability of the manufactures to quickly select a model matching the needs of the site. A city can minimize the cost of buying the product by requiring the different manufacturers to submit bids for the site. All the benefits of the service will have no meaning, however, if the cities cannot trust the performance claims of the different products. Because the United States does not have, at this time, a national program to verify the performance of proprietary SCMs, interested municipalities face a high amount of uncertainty when they select a product. Money could be wasted on products that might have the lowest bid, but do not achieve the water quality goals of the city or state.

The EPA's Environmental Technology Verification (ETV) program was created to facilitate the deployment of innovative or improved environmental technologies through performance verification and dissemination of information. The Wet Weather Flow Technologies Pilot was established as part of the ETV program to verify commercially available technologies used in the abatement and control of urban stormwater runoff, combined sewer overflows, and sanitary sewer overflows. Ten proprietary SCMs were tested under the ETV program (see Figure 5-47), and the results of the monitoring are available on the National Sanitation Foundation International website. Unfortunately, the funding for the ETV program was discontinued before all the stormwater products could be tested. Without a national testing program some states have taken a more regional approach to verifying the performance of proprietary practices, while most states do not have any type of verification or approval program.

The Washington Department of Ecology has supported a testing protocol called Technology Assessment Protocol-Ecology that describes a process for evaluating and reporting on the performance and appropriate uses of emerging SCMs. California, Massachusetts, Maryland, New Jersey, Pennsylvania, and Virginia have sponsored a testing program called Technology Acceptance and Reciprocity Partnership (TARP), and a number of products are being tested in the field. The State of Wisconsin has prepared a draft technical standard (1006) describing methods for predicting the site-specific reduction efficiency of proprietary sedimentation devices. To meet the criteria in the standard the manufacturers can either use a model to predict the performance of the practice or complete a laboratory protocol designed to develop efficiency curves for each product. Although none of these state or federal verification efforts have produced enough information to sufficiently reduce the uncertainty in selection and sizing of proprietary SCMs, many proprietary practices are being installed around the country, because of the perceived advantage of the service being provided by the manufacturers and the sometimes overly optimistic performance claims.

All those involved in stormwater management, including the manufacturers, will have a much better chance of implementing a cost-effective stormwater program in their cities if the barriers to a national testing program for proprietary SCMs are eliminated. Two of the barriers to the ETV program were high cost and the transferability of the results. Also, the ETV testing did not produce results that could be used in developing efficiency curves for the product. A new national testing program could reduce the cost by using laboratory testing instead of field testing. Each manufacturer would only have to do one series of tests in the lab and the results would be applicable to the entire country. The laboratory protocol in the Wisconsin Technical Standard 1006 provides a good example of what should be included to evaluate each practice over a range of particle sizes and flows. These types of laboratory data could also be used to produce efficiency curves for each practice. It would be relatively easy for state and local agencies to review the benefits of each installation if the efficiency curves were incorporated into urban runoff models, such as WinSLAMM or P8.

FIGURE 5-47 Proprietary Manufactured Devices tested by the ETV Program.

Regular maintenance and inspection at a high level are required to remove captured pollutants, to replace mulch, or to rake and remove the surface layer to prevent clogging. In some cases specialized equipment (vacuum trucks) is required to remove built-up sediment. Although the underground placement of these devices has many benefits, it makes it easy to neglect their maintenance because there are no signs of reduced performance on the surface. Because these devices are manufactured, the unit construction cost is usually higher than for other SCMs. Finally, the numerous testing protocols are confusing and prevent more widespread applications.

The chief uncertainty with these SCMs is due to the lack of certification of some manufactured devices. There is also concern about which pollutants are removed by which class

of device. For example, hydrodynamic devices and sand filters do not address dissolved nutrients, and in some cases convert suspended pollutants to their dissolved form. Both issues are related to the false perception that a single SCM must be found that will comprehensively treat stormwater. Such pressures often put vendors in a position of trying to certify that their devices can remove all pollutants. Most often, these devices can serve effectively as part of a treatment train, and should be valued for their incremental contributions to water quality treatment. For example, a filter that removes sediment upstream of a bioinfiltration SCM can greatly prolong the life of the infiltration device.

Aquatic Buffers and Managed Floodplains

Aquatic buffers, sometimes also known as stream buffers or riparian buffers, involve reserving a vegetated zone adjacent to streams, shorelines, or wetlands as part of development regulations or as an ordinance. In most regions of the country, the buffer is managed as forest, although in arid or semi-arid regions it may be managed as prairie, chaparral, or other cover. When properly designed, buffers can both reduce runoff volumes and provide water quality treatment to stormwater.

The performance of urban stream buffers cannot be predicted from studies of buffers installed to remove sediment and nutrients from agricultural areas (Lowrance and Sheridan, 2005). Agricultural buffers have been reported to have high sediment and nutrient removal because they intercept sheet flow or shallow groundwater flow in the riparian zone. By contrast, urban stream buffers often receive concentrated surface runoff or may even have a storm-drain pipe that short-circuits the buffer and directly discharges into the stream. Consequently, the pollutant removal capability of urban stream buffers is limited, unless they are specifically designed to distribute and treat stormwater runoff (NRC, 2000). This involves the use of level spreaders, grass filters, and berms to transform concentrated flows into sheet flow (Hathaway and Hunt, 2006). Such designed urban stream buffers have been applied widely in the Neuse River basin to reduce urban stormwater nutrient inputs to this nitrogen-sensitive waterbody.

The primary benefit of buffers is to help maintain aquatic biodiversity within the stream. Numerous researchers have evaluated the relative impact of riparian forest cover and impervious cover on stream geomorphology, aquatic insects, fish assemblages, and various indexes of biotic integrity. As a group, the studies suggest that indicator values for urban stream health increase when riparian forest cover is retained over at least 50 to 75 percent of the length of the upstream network (Goetz et al., 2003; Wang et al., 2003b; McBride and Booth, 2005; Moore and Palmer, 2005). The width of the buffer is also important for enhancing its stream protection benefits, and it ranges from 25 to 200 feet depending on stream order, protection objectives, and community ordinances. At the present time, there are no data to support an optimum width for water quality purposes. The beneficial impact of riparian forest cover is less detectable when watershed impervious cover exceeds 15 percent, at which point degradation by stormwater runoff overwhelms the benefits of the riparian forest (Roy et al., 2005, 2006; Walsh et al., 2007).

Maintenance, inspection, and compliance for buffers can be a problem. In most communities, urban stream buffers are simply a line on a map and are not managed in any significant way after construction is over. As such, urban stream buffers are prone to residential encroachment and clearing, and to colonization by invasive plants. Another important practice is to protect, preserve, or otherwise manage the ultimate 100-year floodplain so that vulnerable property and infrastructure are not damaged during extreme floods. Federal Emergency

Management Agency (FEMA), state, and local requirements often restrict or control development on land within the floodway or floodplain. In larger streams, the floodway and aquatic buffer can be integrated together to achieve multiple social objectives.

Stream Rehabilitation

While not traditionally considered an SCM, certain stream rehabilitation practices or approaches can be effective at recreating stream physical habitat and ecosystem function lost during urbanization. When combined with effective SCMs in upland areas, stream rehabilitation practices can be an important component of a larger strategy to address stormwater. From the standpoint of mitigating stormwater impacts, four types of urban stream rehabilitation are common:

- Practices that stabilize streambanks and/or prevent channel incision/enlargement can reduce downstream delivery of sediments and attached nutrients (see Figure 5-48). Although the magnitude of sediment delivery from urban-induced stream-channel enlargement is well documented, there are very few published data to quantify the potential reduction in sediment or nutrients from subsequent channel stabilization.
- Streams can be hydrologically reconnected to their floodplains by building up the profile of incised urban streams using grade controls so that the channel and floodplain interact to a greater degree. Urban stream reaches that have been so rehabilitated have increased nutrient uptake and processing rates, and in particular increased denitrification rates, compared to degraded urban streams prior to treatment (Bukavecas, 2007; Kaushal et al., 2008). This suggests that urban stream rehabilitation may be one of many elements that can be considered to help decrease loads in nutrient-sensitive watersheds.
- Practices that enhance in-stream habitat for aquatic life can improve the expected level of stream biodiversity. However, Konrad (2003) notes that improvement of biological diversity of urban streams should still be considered an experiment, since it is not always clear what hydrologic, water quality, or habitat stressors are limiting. Larson et al. (2001) found that physical habitat improvements can result in no biological improvement at all. In addition, many of the biological processes in urban stream ecosystems remain poorly understood, such as carbon processing and nutrient uptake.
- Some stream rehabilitation practices can indirectly increase stream biodiversity (such as riparian reforestation, which could reduce stream temperatures, and the removal of barriers to fish migration).

FIGURE 5-48 Three photographs illustrate stream rehabilitation in Denver. The top left picture is a creek that has eroded in its bed due to urbanization. The top right picture shows a portion of the stabilized creek immediately after construction. Check structures, which keep the creek from cutting its bed, are visible in the middle distance. The bottom image shows the creek just upstream of one of the check structures two years after stabilization. The thickets of willows established themselves naturally. The only revegetation performed was to seed the area for erosion control.

It should be noted that the majority of urban stream rehabilitation projects undertaken in the United States are designed for purposes other than mitigating the impacts of stormwater or enhancing stream biodiversity or ecosystem function (Bernhardt et al., 2005). Most stream rehabilitation projects have a much narrower design focus, and are intended to protect threatened infrastructure, naturalize the stream corridor, achieve a stable channel, or maintain local bank stability (Schueler and Brown, 2004). Improvements in either biological health or the quality of stormwater runoff have rarely been documented.

Unique design models and methods are required for urban streams, compared to their natural or rural counterparts, given the profound changes in hydrologic and sediment regime and stream–floodplain interaction that they experience (Konrad, 2003). While a great deal of design guidance on urban stream rehabilitation has been released in recent years (FISRWG, 2000; Doll and Jennings, 2003; Schueler and Brown, 2004), most of the available guidance has not yet been tailored to produce specific outcomes for stormwater mitigation, such as reduced sediment delivery, increased nutrient processing, or enhanced stream biodiversity. Indeed, several researchers have noted that many urban stream rehabilitation projects fail to achieve even their narrow design objectives, for a wide range of reasons (Bernhardt and Palmer, 2007; Sudduth et al., 2007). This is not surprising given that urban stream rehabilitation is relatively new and rarely addresses the full range of in-stream alteration generated by watershed-scale changes.

This shortfall suggests that much more research and testing are needed to ensure urban stream habilitation can meet its promise as an emerging SCM.

Municipal Housekeeping (Street Sweeping and Storm-Drain Cleanouts)

Phase II NPDES stormwater permits specifically require municipal good housekeeping as one of the six minimum management measures for MS4s. Although EPA has not presented definitive guidance on what constitutes “good housekeeping”, CWP (2008) outlines ten municipal operations where housekeeping actions can improve the quality of stormwater, including the following:

- municipal hotspot facility management,
- municipal construction project management,
- road maintenance,
- street sweeping,
- storm-drain maintenance,
- stormwater hotline response,
- landscape and park maintenance ,
- SCM maintenance, and
- employee training.

The overarching theme is that good housekeeping practices at municipal operations provide source treatment of pollutants before they enter the storm-drain system. The most frequently applied practices are street sweeping (Figure 5-49) and sediment cleanouts of sumps and storm-drain inlets. Most communities conduct both operations at some frequency for safety and aesthetic reasons, although not specifically for the sake of improving stormwater quality (Law et al., 2008).

Numerous performance monitoring studies have been conducted to evaluate the effect of street sweeping on the concentration of stormwater pollutants in downstream storm-drain pipes (see Pitt, 1979; Bender and Terstriep, 1994; Brinkman and Tobin, 2001; Zarrielo et al., 2002; Chang et al., 2005; USGS, 2005; Law et al., 2008). The basic finding is that regular street sweeping has a low or limited impact on stormwater quality, depending on street conditions, sweeping frequency, sweeper technology, operator training, and on-street parking. Sweeping will always have a limited removal capability because rainfall events frequently wash off pollutants before the sweeper passes through, and only some surfaces are accessible to the sweeper, thus excluding sidewalk, driveways, and landscaped areas. Frequent sweeping (i.e., weekly or monthly) has a moderate capability to remove sediment, trash and debris, coarse solids, and organic matter.

Fewer studies have been conducted on the pollutant removal capability of frequent sediment cleanout of storm-drain inlets, most in regions with arid climates (Lager et al., 1977; Mineart and Singh, 1994; Morgan et al., 2005). These studies have shown some moderate pollutant removal if cleanouts are done on a monthly or quarterly basis. Most communities, however, report that they clean out storm drains on an annual basis or in response to problems or drainage complaints (Law, 2006).

FIGURE 5-49 Vacuum street sweeper at Villanova University. SOURCE: Robert Traver.

Frequent sweeping and cleanouts conducted on the dirtiest streets and storm drains appear to be the most effective way to include these operations in the stormwater treatment train. However, given the uncertainty associated with the expected pollutant removal for these practices, street sweeping and storm-drain cleanout cannot be relied on as the sole SCMs for an urban area.

Illicit Discharge Detection and Elimination

MS4 communities must develop a program to detect and eliminate illicit discharges to their storm-drain system as a stormwater NPDES permit condition. Illicit discharges can involve illegal cross-connections of sewage or washwater into the storm-drain system or various intermittent or transitory discharges due to spills, leaks, dumping, or other activities that introduce pollutants into the storm-drain system during dry weather. National guidance on the methods to find and fix illicit discharges was developed by Brown et al. (2004). Local illicit discharge detection and elimination (IDDE) programs represent an ongoing and perpetual effort to monitor the network of pipes and ditches to prevent pollution discharges.

The water quality significance of illicit discharges has been difficult to define since they occur episodically in different parts of a municipal storm drain system. Field experience in conducting outfall surveys does indicate that illicit discharges may be present at 2 to 5 percent of all outfalls at any given time. Given that pollutants are being introduced into the receiving water during dry weather, illicit discharges may have an amplified effect on water quality and biological diversity.

Many communities indicate that they employ a citizen hotline to report illicit discharges and other water quality problems (Brown et al., 2004), which sharply increases the number of illicit discharge problems observed.

Stormwater Education

Like IDDE, stormwater education is one of the six minimum management measures that MS4 communities must address in their stormwater NPDES permits. Stormwater education involves municipal efforts to make sure individuals understand how their daily actions can positively or negatively influence water quality and work to change specific behaviors linked to specific pollutants of concern (Schueler, 2001c). Targeted behaviors include lawn fertilization, littering, car fluid recycling, car washing, pesticide use, septic system maintenance, and pet waste pickup. Communities may utilize a wide variety of messages to make the public aware of the behavior and more desirable alternatives through radio, television, newspaper ads, flyers, workshops, or door-to-door outreach. Several communities have performed before-and-after surveys to assess both the penetration rate for these campaigns and their ability to induce changes in actual behaviors. Significant changes in behaviors have been recorded (see Schueler, 2002), although few studies are available to link specific stormwater quality improvements to the educational campaigns (but see Turner, 2005; CASQA, 2007).

Residential Stewardship

This SCM involves municipal programs to enhance residential stewardship to improve stormwater quality. Residents can undertake a wide range of activities and practices that can reduce the volume or quality of runoff produced on their property or in their neighborhood as a whole. This may include installing rain barrels or rain gardens, planting trees, xeriscaping, downspout disconnection, storm-drain marking, household hazardous waste pickups, and yard waste composting (CWP, 2005). This expands on stormwater education in that a municipality provides a convenient delivery service to enable residents to engage in positive watershed behavior. The effectiveness of residential stewardship is enhanced when carrots are provided to encourage the desired behavior, such as subsidies, recognition, discounts, and technical assistance (CWP, 2005). Consequently, communities need to develop a targeted program to educate residents and help them engage in the desired behavior.

SCM Performance Monitoring and Modeling

Stormwater is characterized by widely fluctuating flows. In addition, inflow pollutant concentrations vary over the course of a storm and can be a function of time since the last storm, watershed, size and intensity of rainfall, season, amount of imperviousness, pollutant of interest, and so forth. This variability of the inflow to SCMs along with the very nature of SCMs makes performance monitoring a complex task. Most SCMs are built to manage stormwater, not to enable flow and water quality monitoring. Furthermore, they are incorporated into the collection system and spread throughout developments. Measurement of multiple inflows, outflows, evapotranspiration, and infiltration are simply not feasible for most sites. Many factors, such as temperature and climate, play a role in how well SCMs function. Infiltration rates can vary by an order of magnitude as a function of temperature (Braga et al., 2007; Emerson and Traver, 2008), such that a reading in late summer might be twice that of a winter reading. Determining performance can be further complicated because, e.g., at the start of a storm a detention basin

could still be partially full from a previous storm, and removal rates for wetlands are a function of the growing season, not to mention snowmelt events.

Monitoring of SCMs is usually performed for one of two purposes: functionality or more intensive performance monitoring. Monitoring of functionality is primarily to establish that the SCM is functioning as designed. Performance monitoring is focused on determining what level of performance is achieved by the SCM.

Functionality Monitoring

Functionality monitoring, in a broad sense, involves checking to see whether the SCM is functioning and screening it for potential problems. Both the federal and several state industrial and construction stormwater general permits have standard requirements for visual inspections following a major storm event. Visual observations of an SCM by themselves do not provide information on runoff reduction or pollutant removal, but rather only that the device is functioning as designed. Adding some grab samples for laboratory analysis can act as a screening tool to determine if a more complex analysis is required.

The first step of functionality monitoring for any SCM is to examine the physical condition of the device (piping, pervious surfaces, outlet structure, etc.). Visual inspection of sediments, eroded berms, clogged outlets, and other problems are good indications of the SCM's functionality (see Figure 5-50). For infiltration devices, visiting after a storm event will show whether or not the device is functioning. A simple staff gauge (Figure 5-51) or a stilling well in pervious pavement can be used to measure the amount of water-level change over several days to estimate infiltration rates. Minnesota suggests the use of fire equipment or hydrants to fill infiltration sites with a set volume of water to measure the rate of infiltration. For sites that are designed to capture a set volume, for example a green roof, a visit could be coordinated with a rainfall event of the appropriate size to determine whether there is overflow during the event. If so, then clearly further investigation is required.

FIGURE 5-50 Rusted outlet structure. SOURCE: Reprinted, with permission, from Emerson. Copyright by Clay Emerson.

FIGURE 5-51 Staff gauge attached to ultrasonic sensor after a storm. SOURCE: VUSP.

For extended detention and stormwater wetlands, the depth of water during an event is an indicator of how well the SCM is functioning. Usually high-water marks are easy to determine due to debris or mud marks on the banks or the structures. If the size of the storm event is known, the depths can be compared to what was expected for the structure. Other indicators of problems would include erosion downstream of the SCM, algal blooms, invasive species, poor water clarity, and odor.

For water quality and manufactured devices, visual inspections after a storm event can determine whether the SCM is functioning properly. Standing water over a sand or other media filter 48 hours after a storm is a sign of problems. Odor and lack of flow clarity could be a sign of filter breakthrough or other problems. For manufactured devices, literature about the device should specify inspection and maintenance procedures.

Monitoring of nonstructural SCMs is almost exclusively limited to visual observation due to the difficulty in applying numerical value to their benefits. Visual inspection can identify eroded stream buffers, additional paved areas, or denuded conservation areas (see Figure 5-52).

Performance Monitoring

Performance monitoring is an extremely intensive effort to determine the performance of an SCM over either an individual storm event or over a series of storms. It requires integration of flow and water quality data creating both a hydrograph and a polutograph for a storm event as shown in Figure 5-53. The creation of these graphs requires continuous monitoring of the hydrology of the site and multiple water quality samples of the SCM inflow and outflow, the vadose zone, and groundwater. Event mean concentrations can then be determined from these data. There should be clear criteria for the number and type of storms to be sampled and for the conditions preceding a storm. For example, for most SCMs it would be improper to sample a second storm event in series, as the inflow may be free of pollutants and the soil moisture filled, resulting in a poor or negative performance. (Extended detention basins are an exception because the outflow during a storm event may include inflows from previous events.) The size of the sampled storm is also important. If the water quality goal is focused on smaller events, the 100-year storm would not give a proper picture of the performance because the occurrence is so rare that it is not a water quality priority.

FIGURE 5-52 Wooded conservation area stripped of trees. Note pile of sawdust. SOURCE: Robert Traver.

FIGURE 5-53 Example polutograph that displays inflow and outflow TSS during a storm event from the Villanova wetland stormwater SCM. SOURCE: Reprinted, with permission, Rea and Traver (2005). Copyright 2005 by the American Society of Civil Engineers.

For runoff-volume-reduction SCMs, performance monitoring can be extremely difficult because these systems are spread over the project site. The monitoring program must consider multiple-size storms because these SCMs are designed to remove perhaps the first inch of runoff. Therefore, for storms of less than an inch, there is no surface water release, so the treatment is 100 percent effective for surface discharges. During larger events, a bioretention SCM or green roof may export pollutants. When viewed over the entire spectrum of storms, these devices are an outstanding success; however, this may not be evident during a hurricane.

Through the use of manufactured weirs (Figure 5-54), it is possible to develop flow-depth criteria based on hydraulic principles for surface flows entering or leaving the SCM. Where this is not practical, various manufacturers have Doppler velocity sensors that, combined with geometry and depth, provide a reasonable continuous record of flow. Measurement of depth within a device can be accomplished through use of pressure transducers, bubblers, float gauges, and ultrasonic sensors. Other common measures would include rainfall and temperature. One advantage of these data recording systems is that they can be connected to water quality probes and automated samplers to provide a flow-weighted sample of the event for subsequent laboratory analysis. Field calibration and monitoring of these systems is required.

FIGURE 5-54 Weir flow used to measure flow rate. Courtesy of Robert Traver.

Groundwater sampling for infiltration SCMs is a challenge. Although the rate of change in water depth can indicate volume moving into the soil mantle, it is difficult to establish whether this flow is evapotranspired or ends up as baseflow or deep groundwater input. Sampling in the vadose zone can be established through the use of lysimeters that, through a vacuum, draw out water from the soil matrix. Soil moisture probes can give a rough estimation of the soil moisture content, and weighing lysimeters can establish evapotranspiration rates. Finally groundwater wells can be used to establish the effect of the SCM on the groundwater depth and quality during and after storm events.

Performance monitoring of extended detention SCMs is difficult because the inflows and outflows are variable and may extend over multiple days. Hydrologic monitoring can be accomplished using weirs (Figure 5-54), flow meters, and level detectors. The new generation of temperature, dissolved oxygen, and conductivity probes allows for automated monitoring. (It should be noted that in many cases the conductivity probes are observing chlorides, which are not generally removed by SCMs.) In many cases monitoring of the downstream stream-channel geomorphology and stream habitat may be more useful than performance monitoring when assessing the effect of the SCM.

The performance monitoring of treatment devices is straightforward and involves determining the pollutant mass inflows and outflows. Performance monitoring of manufactured SCMs has been established through several protocols. An example is TARP, used by multiple states (<http://www.dep.state.pa.us/dep/deputate/pollprev/techservices/tarp/>). This requires the manufacturer to test their units according to a set protocol of lab or field experiments to set performance criteria. Several TARP member and other states have published revised protocols for their use. These and other similar criteria are evolving and the subject of considerable effort by industry organizations that include the American Society of Civil Engineers.

Finally, much needs to be done to determine the performance of nonstructural SCMs, for which little to no monitoring data are available (see Table 5-2). Currently most practitioners expand upon current hydrologic modeling techniques to simulate these techniques. For example, disconnection of impervious surfaces is often modeled by adding the runoff from the roof or parking area as distributed "rainfall" on the pervious area. Experiments and long-term monitoring are needed for these SCMs.

More information on SCM monitoring is available through the International Stormwater BMP Database (<http://www.bmpdatabase.org>).

Modeling of SCM performance

Modeling of SCMs is required to understand their individual performance and their effect on the overall watershed. The dispersed nature of their implementation, the wide variety of possible SCM types and goals, and the wide range of rainfall events they are designed for makes modeling of SCMs extremely challenging. For example, to model multiple SCMs on a single site may require simulation of many hydrologic and environmental processes for each SCM in series. Modeling these effects over large watersheds by simulating each SCM is not only impractical, but the noise in the modeling may make the simulation results suspect. Thus, it is critical to understand the model's purpose, limitations, and applicability.

As discussed in Chapter 4, one approach to simulating SCM performance is through mathematical representation of the unit processes. The large volumes of data needed for process-based models generally restrict their use to smaller-scale modeling. For flow this would start with the hydrograph entering the SCM and include infiltration, evapotranspiration, routing through the system, or whatever flow paths were applicable. The environmental processes that would need to be represented could include settling, adsorption, biological transformation, and soil physics. Currently there are no environmental process models that work across the range of SCMs. Rather, the state of art is to use general removal efficiencies from publications such as the International Stormwater BMP Database (<http://www.bmpdatabase.org>) and the Center for Watershed Protection's National Pollutant Removal Database (CWP, 2000b, 2007b). Unfortunately, this approach has many limitations. The percent removal used on a site and storm basis does not include storm intensity, period between the storms, land use, temperature, management practices, whether other SCMs are upstream, and so forth. It also should be noted that percent removals are a surface water statistic and do not address groundwater issues or include any biogeochemistry.

Mechanistic simulation of the hydrologic processes within an SCM is much advanced compared to environmental simulation, but from a modeling scale it is still evolving. Indeed, models such as the Prince George's County Decision Support System are greatly improved in that the hydrologic simulation of the SCM includes infiltration, but they still do not incorporate the more rigorous soil physics and groundwater interactions. Some models, such as the Stormwater Management Model (SWMM), have the capability to incorporate mechanistic descriptions of the hydrologic processes occurring inside an SCM.

At larger scales, simulation of SCMs is done primarily using lumped models that do not explicitly represent the unit processes but rather the overall effects. For example, the goal may be to model the removal of 2 cm of rainfall from every storm from bioinfiltration SCMs. Thus, all that would be needed is how many SCMs are present and their configuration and what their capabilities are within your watershed. What is critical for these models is to represent the

interrelated processes correctly and to include seasonal effects. Again, the pollutant removal capability of the SCM is represented with removal efficiencies derived from publications.

Regardless of the scale of the model, or the extent to which it is mechanistic or not, nonstructural SCMs are a challenge. Limiting impervious surface or maintenance of forest cover have been modeled because they can be represented as the maintenance of certain land uses.

However, aquatic buffers, disconnected impervious surfaces, stormwater education, municipal housekeeping, and most other nonstructural SCMs are problematic. Another challenge from a watershed perspective is determining what volume of pollutants comes from streambank erosion during elevated flows versus from nonpoint source pollution. Most hydrologic models do not include or represent in-stream processes.

In order to move forward with modeling of SCMs, it will be necessary to better understand the unit processes of the different SCMs, and how they differ for hydrology versus transformations. Research is needed to gather performance numbers for the nonstructural SCMs. Until such information is available, it will be virtually impossible to predict that an individual SCM can accomplish a certain level of treatment and thus prevent a nearby receiving water from violating its water quality standard.

DESIGNING SYSTEMS OF STORMWATER CONTROL MEASURES ON A WATERSHED SCALE

Most communities have traditionally relied on stormwater management approaches that result in the design and installation of SCMs on a site-by-site basis. This has created a large number of individual stormwater systems and SCMs that are widely distributed and have become a substantial part of the contemporary urban and suburban landscape. Typically, traditional stormwater infrastructure was designed on a subdivision basis to reduce peak storm flow rates to predevelopment levels for large flood events (> 10-year return period). The problem with the traditional approach is that (1) the majority of storms throughout the year are small and therefore pass through the detention facilities uncontrolled, (2) the criterion of reducing storm flow does not address the need for reducing total storm volume, and (3) the facilities are not designed to work as a system on a watershed scale. In many cases, the site-by-site approach has exacerbated downstream flooding and channel erosion problems as a watershed is gradually built out. For example, McCuen (1979) and Emerson et al. (2005) showed that an unplanned system of site-based SCMs can actually increase flooding on a watershed scale owing to the effect of many facilities discharging into a receiving waterbody in an uncoordinated fashion—causing the very flooding problem the individual basins were built to solve.

With the relatively recent recognition of unacceptable downstream impacts and the regulation of urban stormwater quality has come a rethinking of the design of traditional stormwater systems. It is becoming rapidly understood that stormwater management should occur on a watershed scale to prevent flow control problems from occurring or reducing the chances that they might become worse. In this context, the “watershed scale” refers to the small local watershed to which the individual site drains (i.e., a few square miles within a single municipality). Together, the developer, designer, plan reviewer, owners, and the municipality jointly install and operate a linked and shared system of distributed practices across multiple sites that achieve small watershed objectives. Many metropolitan areas around the country have institutions, such as the Southeast Wisconsin Regional Planning Commission and the Milwaukee

Metropolitan Sewage District, that are doing stormwater master planning to reduce flooding, bank erosion, and water quality problems on a watershed scale.

Designing stormwater management on a watershed scale creates the opportunity to evaluate a system of SCMs and maximize overall effectiveness based on multiple criteria, such as the incremental costs to development beyond traditional stormwater infrastructure, the limitations imposed on land area required for site planning, the effectiveness at improving water quality or attenuating discharges, and aesthetics. Because the benefits that accrue with improved water quality are generally not realized by those entities required to implement SCMs, greater value must be created beyond the functional aspects of the facility if there is to be wide acceptance of SCMs as part of the urban landscape. Stormwater systems designed on a watershed basis are more likely to be seen as a multi-functional resource that can contribute to the overall quality of the urban environment. Potential even exists to make the stormwater system a primary component of the civic framework of the community—elements of the public realm that serve to enhance a community's quality of life like public spaces and parks. For example, in central Minneapolis, redevelopment of a 100-acre area called Heritage Park as a mixed-density residential neighborhood was organized around two parks linked by a parkway that served dual functions of recreation and stormwater management.

Key elements of the watershed approach to designing systems of SCMs are discussed in detail below. They include the following:

1. Forecasting the current and future development types.
2. Forecasting the scale of current and future development.
3. Choosing among on-site, distributed SCMs and larger, consolidated SCMs.
4. Defining stressors of concern.
5. Determining goals for the receiving water.
6. Noting the physical constraints.
7. Developing SCM guidance and performance criteria for the local watershed.
8. Establishing a trading system.
9. Ensuring the safe performance of the drainage network, streams, and floodplains.
10. Establishing community objectives for the publically owned elements of stormwater infrastructure.
11. Establishing a maintenance plan.

Forecasting the Current and Future Development Types

Forecasting the type of current and future development within the local watershed will guide or shape how individual practices and SCMs are generally assembled at each individual site. The development types that are generally thought of include Greenfield development (small and large scales), redevelopment within established communities and on Brownfield sites, and retrofitting of existing urban areas. These development types range roughly from lower density to higher density impervious cover. Box 5-10 explains how the type of development can dictate stormwater management, discussing two main categories—*Greenfield* development and *redevelopment* of existing areas. The former refers to development that changes pristine or agricultural land to urban or suburban land uses, frequently low-density residential housing. Redevelopment refers to changing from an existing urban land use to another, usually of higher

BOX 5-10

Development Types and their Relationship to the Stormwater System

Development falls into two basic types. Greenfield development requires new infrastructure designed according to contemporary design standards for roads, utilities, and related infrastructure. Redevelopment refers to developed areas undergoing land-use change. In contrast to Greenfields, infrastructure in previously developed areas is often in poor condition, was not built to current design standards, and is inadequate for the new land uses proposed. The stormwater management scenarios common to these types of development are described below.

Greenfield Development

At the largest scale, Greenfield development refers to planned communities at the developing edge of metropolitan areas. Communities of this type often vary from several hundred acres to very large projects that encompassed tens of thousands of acres requiring buildout over decades. They often include the trunk or primary stormwater system as well as open stream and river corridors. The most progressive communities of this type incorporate a significant portion of the area to stormwater systems that exist as surface elements. Such stormwater system elements are typically at the subwatershed scale and provide for consolidated conveyance, detention, and water quality treatment. These elements of the infrastructure can be multi-functional in nature, providing for wildlife habitat, trail corridors, and open-space amenities.

Greenfield development can also occur on a small scale—neighborhoods or individual sites within newly developing areas that are served by the secondary public and tertiary stormwater systems. This smaller-scale, incremental expansion of existing urban patterns is a more typical way for cities to grow. A more limited range of SCMs and innovative stormwater management practices are available on smaller projects of this type, including LID practices.

Redevelopment of Existing Areas

Redevelopment within established communities is typically at the scale of individual sites and occasionally the scale of a small district. The area is usually served by private, on-site systems that convey larger storm events into preexisting stormwater systems that were developed decades ago, either in historic city centers or in "first ring," post-World War II suburbs adjacent to historic city centers. Redevelopment in these areas is typically much denser than the original use. The resulting increase in impervious area, and typically the inadequacy of existing stormwater infrastructure serving the site often results in significant development costs for on-site detention and water quality treatment. Elaborate vaults or related structures, or land area that could be utilized for development, must often be committed to on-site stormwater management to comply with current stormwater regulations.

Brownfields are redevelopments of industrial and often contaminated property at the scale of an individual site, neighborhood, or district. Secondary public systems and private stormwater systems on individual sites typically serve these areas. In many cases, especially in outdated industrial areas, little or no stormwater infrastructure exists, or it is so inadequate as to require replacement. Water quality treatment on contaminated sites may also be necessary. For these reasons, stormwater management in such developments presents special challenges. As an example, the most common methods of remediation of contaminated sites involve capping of contaminated soils or treatment of contaminants in situ, especially where removal of contaminated soils from a site is cost prohibitive. Given that contaminants are still often in place on redeveloped Brownfield sites and must not be disturbed, certain SCMs such as infiltration of stormwater into site soils, or excavation for stormwater piping and other utilities, present special challenges.

density, such as from single-family housing to multi-family housing. Finally, *retrofitting* as used in this report is not a development type but rather the upgrading of stormwater management within an existing land use to meet higher standards.

Table 5-7 shows which SCMs are best suited for Greenfield development (particularly low-density residential), redevelopment of urban areas, and intense industrial redevelopment. The last category is broken out because the suite of SCMs needed is substantially different than for urban redevelopment. Each type of development has a different footprint, impervious cover, open space, land cost, and existing stormwater infrastructure. Consequently, SCMs that are ideally suited for one type of development may be impractical or infeasible for another. One of the main points to be made is that there are more options during Greenfield development than during redevelopment because of existing infrastructure, limited land area, and higher costs in the latter case.

Forecasting the Scale of Current and Future Development

The choice of what SCMs to use depends on the area that needs to be serviced. It turns out that some SCMs work best over a few acres, whereas others require several dozen acres or more; some are highly effective only for the smallest sites, while others work best at the stream corridor or subwatershed level. Table 5-1 includes a column that is related the scale at which individual SCMs can be applied ("where" column). The SCMs mainly applied at the site scale include runoff volume reduction—rainwater harvesting, runoff treatment like filtering, and pollution prevention SCMs for hotspots. As one goes up in scale, SCMs like runoff volume reduction—vegetated and subsurface, earthwork minimization, and erosion and sediment control take on more of a role. At the largest scales, watershed and land-use planning, conservation of natural areas, reforestation and soil conservation, peak flow reduction, buffers and managed floodplains, stream rehabilitation, municipal housekeeping, IDDE, stormwater education, and residential stewardship play a more important role. Some SCMs are useful at all scales, such as product substitution and impervious cover minimization.

Choosing Among On-Site, Distributed SCMs and Larger, Consolidated SCMs

There are distinct advantages and disadvantages to consider when choosing to use a system of larger, consolidated SCMs versus smaller-scale, on-site SCMs that go beyond their ability to achieve water quality or urban stream health. Smaller, on-site facilities that serve to meet the requirements for residential, commercial, and office developments tend to be privately owned. Typically, flows are directed to porous landscape detention areas or similar SCMs, such that volume and pollutants in stormwater are removed at or near their source. Quite often, these SCMs are relegated to the perimeter project, incorporated into detention ponds, or, at best, developed as landscape infiltration and parking islands and buffers. On-site infiltration of frequent storm events can also reduce the erosive impacts of stormwater volumes on downstream receiving waters. Maintenance is performed by the individual landowner, which is both an advantage because the responsibility and costs for cleanup of pollutants generated by individual properties are equitably distributed, and a disadvantage because ongoing maintenance incurs a significant expense on the part of individual property owners and enforcement of properties not in compliance with required maintenance is difficult. On the negative side, individual SCMs often require additional land, which increases development costs and can encourage sprawl. Monitoring of thousands of SCMs in perpetuity in a typical city creates a significant ongoing public expense, and special training and staffing may be required to maintain SCM effectiveness (especially for subgrade or in-building vaults used in ultra-urban environments). Finally, given that as much as 30 percent of the urban landscape is comprised of public streets and rights-of-way, there are limited opportunities to treat runoff from streets through individual on-site private SCMs. (Notable exceptions are subsurface runoff-volume-reduction SCMs like permeable pavement that require no additional land and promote full development density within a given land parcel because they use the soil areas below roads and the development site for infiltration.)

In contrast, publicly owned, consolidated SCMs are usually constructed as part of larger Greenfield and infill development projects in areas where there is little or no existing infrastructure. This type of facility—usually an infiltration basin, detention basin, wet/dry pond, or stormwater wetland—tends to be significantly larger, serving multiple individual properties.

Ownership is usually by the municipality, but may be a privately managed, quasi-public special district. There must be adequate land available to accommodate the facility and a means of up-front financing to construct the facility. An equitable means of allocating costs for ongoing maintenance must also be identified. However, the advantage of these facilities is that consolidation requires less overall land area, and treatment of public streets and rights-of-way can be addressed. Monitoring and maintenance are typically the responsibility of one organization, allowing for effective ongoing operations to maintain the original function of the facility. If that entity is public, this ensures that the facility will be maintained in perpetuity, allowing for the potential to permanently reduce stormwater volumes and for reduction in the size of downstream stormwater infrastructure. Because consolidated facilities are typically larger than on-site SCMs, mechanized maintenance equipment allows for greater efficiency and lower costs. Finally, consolidated SCMs have great potential for multifunctional uses because wildlife habitat, recreational, and open-space amenities can be integrated to their design. Box 5-11 describes sites of various scales where either consolidated or distributed SCMs were chosen.

Defining Stressors of Concern

The primary pollutants or stressors of concern (and the primary source areas or stormwater hotspots within the watershed likely to produce them) should be carefully defined for the watershed. Although this community decision is made only infrequently, it is critical to ensuring that SCMs are designed to prevent or reduce the maximum load of the pollutants of greatest concern. This choice may be guided by regional water quality priorities (such as nutrient reduction in the Chesapeake Bay or Neuse River watersheds) or may be an outgrowth of the total maximum daily load process where there is known water quality impairment or a listed pollutant. The choice of a pollutant of concern is paramount, since individual SCMs have been shown to have highly variable capabilities to prevent or reduce specific pollutants (see WERF, 2006; ASCE, 2007; CWP, 2007b). In some cases, the capability of SCMs to reduce a specific pollutant may be uncertain or unknown.

Determining Goals for the Receiving Waters

It is important to set biological and public health goals for the receiving water that are achievable given the ultimate impervious cover intended for the local watershed (see the Impervious Cover Model in Box 3-10). If the receiving water is too sensitive to meet these goals, one should consider adjustments to zoning and development codes to reduce the amount of impervious cover. The biological goals may involve a keystone species, such as salmon or trout, a desired state of biological integrity in a stream, or a maximum level of eutrophication in a lake. In other communities, stormwater goals may be driven by the need to protect a sole-source drinking water supply (e.g., New York watersheds) or to maintain water contact recreation at a beach, lake, or river. Once again, the watershed goals that are selected have a strong influence on the assembly of SCMs needed to meet them, since individual SCMs vary greatly in their ability to achieve different biological or public health outcomes.

BOX 5-11
Examples of Communities Using Consolidated versus Distributed SCMs

Stapleton Airport New Community

This is a mixed-use, mixed-density New Urbanist community that has been under development for the past 15 years on the 4,500-acre former Stapleton Airport site in central Denver. As shown in Figures 5-55 and 5-56, the stormwater system emphasizes surface conveyance and treatment on individual sites, as well as in consolidated regional facilities.

FIGURE 5-55 The community plan, shown on the left, is organized around two day lighted creeks, formerly buried under airport runways, and a series of secondary conveyances which provide recreational open space within neighborhoods. The image on the right illustrates one of the multi-functional creek corridors. Consolidated stormwater treatment areas and surface conveyances define more traditional park recreation and play areas. Courtesy of Stapleton Redevelopment Foundation.

FIGURE 5-56 A consolidated treatment area adjacent to one of several neighborhoods that have been constructed as part of the project's build-out.

Heritage Park Neighborhood Redevelopment

A failed public housing project adjacent to downtown Minneapolis, Minnesota, has been replaced by a mixed-density residential neighborhood. Over 1,200 rental, affordable, and market-rate single- and multi-family housing units have been provided in the 100-acre project area. The neighborhood is organized around two neighborhood parks and a parkway that serve dual functions as neighborhood recreation space and as surface stormwater conveyance and a consolidated treatment system (see Figure 5-57). Water quality treatment is being provided for a combined area of over 660 acres that includes the 100-acre project area and over 500 acres of adjacent neighborhoods. Existing stormwater pipes have been routed through treatment areas with treatment levels ranging from 50 to 85 percent TSS removal, depending on the available land area.

FIGURE 5-57 View of a sediment trap and porous landscape detention area in the central parkway spine of Heritage Park. The sediment trap in the center left of the photo was designed for ease of maintenance access by city crews with standard city maintenance equipment. Courtesy of SRF Consulting Group, Inc.

The High Point Neighborhood

This Seattle project is the largest example of the city's Natural Drainage Systems Project and it illustrates the incorporation of individual SCMs into street rights-of-way as well as a consolidated facility. The on-site, distributed SCMs in this 600-acre neighborhood are swales, permeable pavement, and disconnected downspouts. A large detention pond services the entire region that is much smaller than it would have been had the other SCMs not been built. Both types of SCMs are shown in Figure 5-58.

FIGURE 5-58 Natural drainage system methods have been applied to a 34-block, 1,600-unit mixed-income housing redevelopment project called High Point. Vegetated swales, porous concrete sidewalks, and frontyard rain gardens convey and treat stormwater on-site. On the right is the detention pond for the development.

BOX 5-11 Continued

Potsdammer Platz

This project, in the heart of Berlin, Germany, illustrates the potential for stormwater treatment in the densest urban environments by incorporating treatment into building systems and architectural pools that are the centerpiece of a series of urban plazas. As shown in Figure 5-59, on-site, individual SCMs are used to collect stormwater and use it for sanitary purposes.

FIGURE 5-59 Stormwater is collected and stored on-site in a series of vaults. Water is circulated through a series of biofiltration areas and used for toilets and other mechanical systems in the building complex. Large storms overflow into an adjacent canal. Permission pending.

Menomonee Valley Redevelopment, Wisconsin

The 140-acre redevelopment of abandoned railyards illustrates how a Brownfield site within an existing floodplain can be redeveloped using both on-site and consolidated treatment. As shown in Figure 5-60, consolidated treatment is incorporated into park areas which provide recreation for adjacent neighborhoods and serve as a centerpiece for a developing light industrial area that provides jobs to surrounding neighborhoods. Treatment on individual privately owned parcels is limited to the removal of larger sediments and debris only, making more land available for development. The volume of water that, by regulation, must be captured and treated on individual sites is conveyed through a conventional subsurface system for treatment in park areas.

FIGURE 5-60 Illustrations show consolidated treatment areas in proposed parks. The image on the left illustrates the fair weather condition, the center image the water quality capture volume, and the image on the right the 100-year storm event. Construction was completed in spring 2007.

Noting the Physical Constraints

The specific physical constraints of the watershed terrain and the development pattern will influence the selection and assembly of SCMs. The application of SCMs must be customized in every watershed to reflect its unique terrain, such as karst, high water tables, low or high slopes, freeze-thaw depth, soil types, and underlying geology. Each SCM has different restrictions or constraints associated with these terrain factors. Consequently, the SCM prescription changes as one moves from one physiographic region to another (e.g., the flat coastal plain, the rolling Piedmont, the ridge and valley, and mountainous headwaters).

Developing SCM Guidance and Performance Criteria for the Local Watershed

Based on the foregoing factors, the community should establish specific sizing, selection, and design requirements for SCMs. These SCM performance criteria may be established in a local, regional, or state stormwater design manual, or by reference in a local watershed plan. The Minnesota Stormwater Steering Committee (MSSC, 2005) provides a good example of how SCM guidance can be customized to protect specific types of receiving waters (e.g., high-quality lakes, trout streams, drinking water reservoirs, and impaired waters). In general, the watershed- or receiving water-based criteria are more specific and detailed than would be found in a regional or statewide stormwater manual. For example, the local stormwater guidance criteria may be more prescriptive with respect to runoff reduction and SCM sizing requirements, outline a preferred sequence for SCMs, and indicate where SCMs should (or should not) be located in the watershed. Like the identification of stressors or pollutants of concerns, this step is rarely taken under current paradigms of stormwater management.

Establishing a Trading System

A stormwater trading or offset system is critical to situations when on-site SCMs are not feasible or desirable in the watershed. Communities may choose to establish some kind of stormwater trading or mitigation system in the event that full compliance is not possible due to physical constraints or because it is more cost effective or equitable to achieve pollutant reduction elsewhere in the local watershed. The most common example is providing an offset fee based on the cost to remove an equivalent amount of pollutants (such as phosphorus in the Maryland Critical Area—MD DNR, 2003). This kind of trading can provide for greater cost equity between low-cost Greenfield sites and higher-cost ultra-urban sites.

Ensuring the Safe and Effective Performance of the Drainage Network, Streams, and Floodplains

The urban water system is not solely designed to manage the quality of runoff. It also must be capable of safely handling flooding from extreme storms to protect life and property. Consequently, communities need to ensure that their stormwater infrastructure can prevent increased flooding caused by development (and possibly exacerbated future climate change). In

addition, many SCMs must be designed to safely pass extreme storms when they do occur. This usually requires a watershed approach to stormwater management to ensure that quality and quantity control are integrated together, with an emphasis on the connection and effective use of conveyance channels, streams, riparian buffers, and floodplains.

Establishing Community Objectives for the Publicly Owned Elements of Stormwater Infrastructure

The stormwater infrastructure in a community normally occupies a considerable surface area of the landscape once all the SCMs, drainage easements, buffers, and floodplains are added together. Consequently, communities may require that individual SCM elements are designed to achieve multiple objectives, such as landscaping, parks, recreation, greenways, trails, habitat, sustainability, and other community amenities (as discussed extensively above). In other cases, communities may want to ensure that SCMs do not cause safety or vector problems and that they look attractive. The best way to maximize community benefits is to provide clear guidance in local SCM criteria at the site level and to ensure that local watershed plans provide an overall context for their implementation.

Establishing an Inspection and Maintenance Plan

The long-term performance of any SCM is fundamentally linked to the frequency of inspections and maintenance. As a result, NPDES stormwater permit conditions for industrial, construction, and municipal permittees specify that pollution prevention, construction, and post-construction SCMs be adequately maintained. MS4 communities are also required under NPDES stormwater permits to track, inspect, and ensure the maintenance of the collective system of SCMs and stormwater infrastructure within their jurisdiction. In larger communities, this can involve hundreds or even thousands of individual SCMs located on either public or private property. In these situations, communities need to devise a workable model that will be used to operate, inspect, and maintain the stormwater infrastructure across their local watershed. Communities have the lead responsibility in their MS4 permits to assure that SCMs are maintained properly to ensure their continued function and performance over time. They can elect to assign the responsibility to the public sector, the private sector (e.g., property owners and homeowners association), or a hybrid of the two, but under their MS4 permits they have ultimate responsibility to ensure that SCM maintenance actually occurs. This entails assigning legal and financial responsibilities to the owners of each SCM element in the watershed, as well as maintaining a tracking and enforcement system to ensure compliance.

Summary

Taking all of the elements above into consideration, the emerging goal of stormwater management is to mimic, as much as possible, the hydrological and water quality processes of natural systems as rain travels from the roof to the stream through combined application of a series of practices throughout the entire development site and extending to the stream corridor.

The series of SCMs incrementally reduces the volume of stormwater on its way to the stream, thereby reducing the amount of conventional stormwater infrastructure required.

There is no single SCM prescription that can be applied to each kind of development; rather, a combination of interacting practices must be used for full and effective treatment. For a low-density residential Greenfield setting, a combination of SCMs that might be implemented is illustrated in Table 5-8. There are many successful examples of SCMs in this context and at different scales. By contrast, Tables 5-9 and 5-10 outline how the general “roof-to-stream” stormwater approach is adapted for intense industrial operations and urban redevelopment sites, respectively. As can be seen, these development situations require a differ combination of SCMs and practices to address the unique design challenges of dense urban environments. The tables are meant to be illustrative of certain situations; other scenarios, such as commercial development, would likely require additional tables.

TABLE 5-8 From the Roof to the Stream: SCMs in a Residential Greenfield

SCM	What it Is	What it Replaces	How it Works
Land-Use Planning	Early site assessment	Doing SWM design after site layout	Map and plan submitted at earliest stage of development review showing environmental, drainage, and soil features
Conservation of Natural Areas	Maximize forest canopy	Mass clearing	Preservation of priority forests and reforestation of turf areas to intercept rainfall
Earthwork Minimization	Conserve soils and contours	Mass grading and soil compaction	Construction practices to conserve soil structure and only disturb a small site footprint
Impervious Cover Minimization	Better site design	Large streets, lots and cul-de-sacs	Narrower streets, permeable driveways, clustering lots, and other actions to reduce site IC
Runoff Volume Reduction—Rainwater Harvesting	Utilize rooftop runoff	Direct connected roof leaders	A series of practices to capture, disconnect, store, infiltrate, or harvest rooftop runoff
Runoff Volume Reduction—Vegetated	Frontyard bioretention	Positive drainage from roof to road	Grading frontyard to treat roof, lawn, and driveway runoff using shallow bioretention
	Dry swales	Curb/gutter and storm drain pipes	Shallow, well-drained bioretention swales located in the street right-of-way
Peak Reduction and Runoff Treatment	Linear wetlands	Large detention ponds	Long, multi-cell, forested wetlands located in the stormwater conveyance system
Aquatic Buffers and Managed Floodplains	Stream buffer management	Unmanaged stream buffers	Active reforestation of buffers and restoration of degraded streams

Note: SCMs are applied in a series, although all of the above may not be needed at a given residential site. This “roof-to-stream” approach works best for low- to medium-density residential development.

In summary, a watershed approach for organizing site-based stormwater decisions is generally superior to making site-based decisions in isolation. Communities that adopt the preceding watershed elements not only can maximize the performance of the entire system of SCMs to meet local watershed objectives, but also can maximize other urban functions, reduce total costs, and reduce future maintenance burdens.

TABLE 5-9 From the Roof to the Outfall: SCMs in an Industrial Context

SCM Category	What it Is	What it Replaces	How it Works
Pollution Prevention	Drainage mapping	No map	Analysis of the locations and connections of the stormwater and wastewater infrastructure from the site
	Hotspot site investigation	Visual inspection	Systematic assessment of runoff problems and pollution prevention opportunities at the site
	Rooftop management	Uncontrolled rooftop runoff	Use of alternative roof surfaces or coatings to reduce metal runoff, and disconnection of roof runoff for stormwater treatment
	Exterior maintenance practices	Routine plant maintenance	Special practices to reduce discharges during painting, powerwashing, cleaning, sealcoating and sandplasting
	Extending roofs for no exposure	Exposed hotspot operations	Extending covers over susceptible loading/unloading, fueling, outdoor storage, and waste management operations
	Vehicular pollution prevention	Uncontrolled vehicle operations	Pollution prevention practices applied to vehicle repair, washing, fueling, and parking operations
	Outdoor pollution prevention practices	Outdoor materials storage	Prevent rainwater from contact with potential pollutants by covering, secondary containment, or diversion from storm-drain system
	Waste management practices	Exposed dumpster or waste streams	Improved dumpster location, management, and treatment to prevent contact with rainwater or runoff
	Spill control plan and response	No plan	Develop and test response to spills to the storm-drain system, train employees, and have spill control kits available on-site
	Greenscaping	Routine landscape and turf maintenance	Reduce use of pesticides, fertilization, and irrigation in pervious areas, and conversion of turf to forest
	Employee stewardship	Lack of stormwater awareness	Regular ongoing training of employees on stormwater problems and pollution prevention practices
Site housekeeping and stormwater maintenance	Dirty site and unmaintained infrastructure	Regular sweeping, storm-drain cleanouts, litter pickup, and maintenance of stormwater infrastructure	
Runoff Treatment	Stormwater retrofitting	No stormwater treatment	Filtering retrofits to remove pollutants from most severe hotspot areas
IDDE	Outfall analysis	No monitoring	Monitoring of outfall quality to measure effectiveness

Note: While many SCMs are used at each individual industrial site, the exact combination depends on the specific configuration, operations, and footprint of each site.

TABLE 5-10 From the Roof to the Street: SCMs in a Redevelopment Context

SCM Category	What it Is	What it Replaces	How it Works
Impervious Cover Minimization	Site design to prevent pollution	Conventional site design	Designing redevelopment footprint to restore natural area remnants, minimize needless impervious cover, and reduce hotspot potential
Runoff Volume Reduction—Rainwater Harvesting and Vegetated	Treatment on the roof	Traditional rooftops	Use of green rooftops to reduce runoff generated from roof surfaces
	Rooftop runoff treatment	Directly connected roof leaders	Use of rain tanks, cisterns, and rooftop disconnection to capture, store, and treat runoff
	Runoff treatment in landscaping	Traditional landscaping	Use of foundation planters and bioretention areas to treat runoff from parking lots and rooftops
Soil Conservation and Reforestation	Runoff reduction in pervious areas	Impervious or compacted soils	Reducing runoff from compacted soils through tilling and compost amendments, and in some cases, removal of unneeded impervious cover
	Increase urban tree canopy	Turf or landscaping	Providing adequate rooting volume to develop mature tree canopy to intercept rainfall
Runoff Reduction—Subsurface	Increase permeability of impervious cover	Hard asphalt or concrete	Use of permeable pavers, porous concrete, and similar products to decrease runoff generation from parking lots and other hard surfaces.
Runoff Reduction—Vegetated	Runoff treatment in the street	Sidewalks, curb and gutter, and storm drains	Use of expanded tree pits, dry swales and street bioretention cells to further treat runoff in the street, or its right-of-way
Runoff Treatment	Underground treatment	Catch basins and storm-drain pipes	Use of underground sand filters and other practices to treat hotspot runoff quality at the site
Municipal Housekeeping	Street cleaning	Unswep streets	Targeted street cleaning on priority streets to remove trash and gross solids
Watershed Planning	Off-site stormwater treatment or mitigation	On-site waivers	Stormwater retrofits or restoration projects elsewhere in the watershed to compensate for stormwater requirements that cannot be met onsite

Note: SCMs are applied in a series, although all of the above may not be needed at a given redevelopment site.

COST, FINANCE OPTIONS, AND INCENTIVES

Municipal Stormwater Financing

To be financially sustainable, stormwater programs must develop a stable long-term funding source. The activities common to most municipal stormwater programs (such as education, development design review, inspection, and enforcement) are funded through general tax revenues, most commonly property taxes and sales taxes (NAFSMA, 2006), which is problematic for several reasons. First, stormwater management financed through general tax receipts does not link or attempt to link financial obligation with services received. The absence of such links can reduce the ability of a municipality to adequately plan and meet basic stormwater management obligations. Second, when funded through general tax revenues, stormwater programs must compete with other municipal programs and funding obligations. Finally, in programs funded by general tax revenue, responsibilities for stormwater management tend to be distributed into the work responsibilities of existing and multiple departments (e.g., public works, planning, etc.). One recent survey conducted in the Charles River watershed in Massachusetts found that three-quarters of local stormwater management programs did not have staff dedicated exclusively for stormwater management (Charles River Watershed Association, 2007).

Increasingly, many municipalities are establishing stormwater utilities to manage stormwater (Kaspersen, 2000). Most stormwater utilities are created as a separate organizational entity with a dedicated, self-sustaining source of funding. The typical stormwater utility generates the large majority of revenue through user fees (Florida Stormwater Association, 2003; Black and Veatch, 2005; NAFSMA, 2006). User fees are established and set so as to have a close nexus to the cost of providing the service and, thus, are most commonly based on the amount of impervious surface, frequently measured in terms of equivalent residential unit. For example, an average single-family residence may create 3,000 square feet of impervious surface (roof and driveway area). A per-unit charge is then assigned to this "equivalent runoff unit." To simplify program administration, utilities typically assign a flat rate for residential properties (customer class average) (NAFSMA, 2006). Nonresidential properties are then charged individually based on the total amount of impervious surface (square feet or equivalent runoff units) of the parcel. Fees are sometimes also based on gross area (total area of a parcel) or some combination of gross area and a development intensity measure (Duncan, 2004; NAFSMA, 2006).

Municipalities have the legal authority to create stormwater utilities in most states (Lehner et al., 1999). In addition to creating the utility, a municipality will generally establish the utility rate structure in a separate ordinance. Separating the ordinances allows the municipality flexibility to change the rate structure without revising the ordinance governing the entire utility (Lehner et al., 1999). While municipalities generally have the authority to collect fees, some states have legal restrictions on the ability of local governments to levy taxes (Lehner et al., 1999; NAFSMA, 2006). The legal distinction between a tax and a fee is the most common legal challenge to a stormwater utility. For example, stormwater fees have been subject to litigation in at least 17 states (NAFSMA, 2006). To avoid legal challenges, care must be taken to meet a number of legal tests that distinguish a fee for a specific service and a general tax.

Stormwater utilities typically bill monthly, and fees range widely. A recent survey of U.S. stormwater utilities reported that fees for residential households range from \$1 to \$14 per month, but a typical residential household rate is in the range of \$3 to \$6 (Black and Veatch, 2005). Despite the dedicated funding source, the majority of stormwater utilities responding to a recent survey (55 percent) indicated that current funding levels were either inadequate or just adequate to meet their most urgent needs (Black and Veatch, 2005).

Both municipal and state programs can finance administrative programming costs through stormwater permitting fees. Municipal stormwater programs can use separate fees to finance inspection activities. For instance, inspection fees can be charged to cover the costs of ensuring that SCMs are adequately planned, installed, or maintained (Debo and Reese, 2003). Stormwater management programs can also ensure adequate funding for installation and maintenance of SCMs by requiring responsible parties to post financial assurances. Performance bonds, letters of credit, and cash escrow are all examples of financial assurances that require up-front financial payments to ensure that longer-term actions or activities are successfully carried out. North Carolina's model stormwater ordinance recommends that the amount of a maintenance performance security (bond, cash escrow, etc.) be based on the present value of an annuity based on both inspection costs and operation and maintenance costs (Whisnant, 2007).

In addition to fees or taxes, exactions such as impact fees can also be used as a way to finance municipal stormwater infrastructure investments (Debo and Reese, 2003). An impact fee is a one-time charge levied on new development. The fee is based on the costs to finance the infrastructure needed to service the new development. The ability to levy impact fees varies between states. Municipalities that use impact fees are also required to show a close nexus between the size of the fee and the level of benefits provided by the fee; a failure to do so exposes local government to law suits (Keller, 2003). Compared to other funding sources, impact fees also exhibit greater variability in revenue flows because the amount of funds collected is dependent on development growth.

Bonds and grants can supplement the funding sources identified above. Bonds and loans tend to smooth payments over time for large up-front stormwater investments. For example, state and federal loan programs (state revolving funds) provide long-term, low-interest loans to local governments or capital investments (Keller, 2003). In addition, grant opportunities are sometimes available from state and federal sources to help pay for specific elements of local stormwater management programs.

Municipalities require funds to meet federal and state stormwater requirements. Understanding of the municipal costs incurred by implementing stormwater regulations under the Phase I and II stormwater rules, however, is incomplete (GAO, 2007). Of the six minimum measures of a municipal stormwater program (public education, public involvement, illicit discharge detection and elimination, construction site runoff control, post-construction stormwater management, and pollution prevention/good housekeeping—see Chapter 2), a recent study of six California municipalities found that pollution prevention activities (primarily street sweeping) accounted for over 60 percent of all municipal stormwater management costs in these communities (Currier et al., 2005). Annual per-household costs ranged from \$18 to \$46.

Stormwater Cost Review

Conceptually, the costs of providing SCMs are all opportunity costs (EPA, 2000). Opportunity costs are the value of alternatives (next best) given up by society to achieve a particular outcome. In the case of stormwater control, opportunity costs include direct costs necessary to control and treat runoff such as capital and construction costs and the present value of annual operation and maintenance costs. Initial installation costs should also include the value of foregone opportunities on the land used for stormwater control, typically measured as land acquisition (land price).

Costs also include public and private resources incurred in the administration of the stormwater management program. Private-sector costs might include time and administrative costs associated with permitting programs. Public costs include agency monitoring and enforcement costs.

Opportunity costs also include other values that might be given up as a consequence of stormwater management. For example, the creation of a wet pond in a residential area might be opposed because of perceived safety, aesthetic, or nuisance concerns (undesirable insect or animal species). In this case, the diminished satisfaction of nearby property owners is an opportunity cost associated with the wet pond. On the other hand, if SCMs are considered a neighborhood amenity (e.g., a constructed wetland in a park setting), opportunity costs may decrease. In addition, costs of a given practice may be reduced by reducing costs elsewhere. For example, increasing on-site infiltration rates can reduce off-site storage costs by reducing the volume and slowing the release of runoff.

In general the cost of SCMs is incompletely understood and significant gaps exist in the literature. More systematic research has been conducted on the cost of conventional stormwater SCMs (wet ponds, detention basins, etc.), with less research applied to more recent, smaller-scale, on-site infiltration practices. Cost research is challenging given that stormwater treatment exhibits considerable site-specific variation resulting from different soil, topography, climatic conditions, local economic conditions, and regulatory requirements (Lambe et al., 2005).

The literature on stormwater costs tend to be oriented around construction costs of particular types of SCMs (Wiegand et al., 1986; SWRPC, 1991; Brown and Schueler, 1997; Heaney et al., 2002; Sample et al., 2003; Wossink and Hunt, 2003; Caltrans, 2004; Narayanan and Pitt, 2006; DeWoody, 2007). In many of these studies, construction cost functions are estimated statistically based on a sample of recently installed SCMs and the observed total construction costs. Observed costs are then related statistically to characteristics that influence cost such as practice size. Other studies estimate costs by identifying the individual components of a construction project (pipes, excavation, materials, labor, etc.), estimating unit costs of each component, and then summing all project components. These studies generally find that construction costs decrease on a per-unit basis as the overall size (expressed in volume or drainage area) of the SCM increases (Lambe et al., 2005). These within-practice economies of scale are found across certain SCMs including wet ponds, detention ponds, and constructed wetlands. Several empirical studies, however, failed to find evidence of economies of scale for bioretention practices (Brown and Schueler, 1997; Wossink and Hunt, 2003).

Increasing attention has been paid to small-scale practices, including efforts to increase infiltration and retain water through such means as green roofs, permeable pavements, rain barrels, and rain gardens (under the label of LID). The costs of these practices are less well studied compared to the other stormwater practices identified above. In general, per-unit

construction and design costs exceed larger-scale SCMs (Low Impact Development Center, 2007). Higher construction costs, however, may be offset to various degrees by reducing the investments in stormwater conveyance and storage infrastructure (i.e., less storage volume is needed) (CWP, 1998a, 2000a; Low Impact Development Center, 2007). Others have suggested that per-unit costs to reduce runoff may be less for these small-scale distributed practices because of higher infiltration rates and retention rates (MacMullan and Reich, 2007).

Compared to construction costs, less is known about the operation and maintenance costs of SCMs (Wossink and Hunt, 2003; Lambe et al., 2005; MacMullan and Reich, 2007). Most stormwater practices are not maintenance free and can create financial and long-term management obligations for responsible parties (Hager, 2003). Cost-estimation programs and procedures have been developed to estimate operation and maintenance costs as well as construction costs (SWRPC, 1991; Lambe et al., 2005; Narayanan and Pitt, 2006), but examination of observed maintenance costs is less common. Based on estimates from Wossink and Hunt (2003), the total present value of maintenance costs over 20 years can range from 15 to 70 percent of total capital construction costs for wet ponds and constructed wetlands and appear generally consistent with percentages reported in EPA (1999). Operation and maintenance costs were also reported to be a substantial percentage of construction costs of infiltration pits and bioretention areas in Southern California (DeWoody, 2007). Others estimate that over the life of many SCMs, maintenance costs may equal construction costs (CWP, 2000a). In general, maintenance costs tend to decrease as a percentage of total SCM cost as the total size of the SCM increases (Wossink and Hunt, 2003).

Very few quantifiable estimates are available for public and private regulatory compliance costs. Compliance costs could include both initial permitting costs (labor and time delays) of gaining regulatory approval for a particular stormwater design to post-construction compliance costs (administration, inspection monitoring, and enforcement). Compliance monitoring is a particular concern if a stormwater management program relies on widespread use of small-scale distributed on-site practices (Hager, 2003). Unlike larger-scale or regional stormwater facilities that might be located on public lands or on private lands with an active stormwater management plan, a multitude of smaller SCMs would increase monitoring and inspection times by increasing the number of SCMs. Furthermore, municipal governments may be reluctant to undertake enforcement actions against citizens with SCMs located on private land.

Land costs tend to be site specific and exhibit a great deal of spatial variation. Some types of SCMs, such as constructed wetlands, are more land intensive than others. In highly urban areas, land costs may be the single biggest cost outlay of land-intensive SCMs (Wossink and Hunt, 2003).

In general, cost analyses generally find that the cost to treat a given acreage or volume of water is less for regional SCMs than for smaller-scale SCMs (Brown and Schueler, 1997; EPA, 1999; Wossink and Hunt, 2003). For example, considering maintenance, capital construction, and land costs, recent estimates for North Carolina indicate that annual costs for wet ponds and constructed wetlands range between \$100 and \$3,000 per treated acre (typically less than \$1,000). Per-acre annual costs for bioretention and sand filters typically ranged between \$300 and \$3,500, and between \$4,500 and 8,500, respectively. However, if SCMs face space constraints, bioretention areas can become more cost effective. Furthermore, other classes of small, on-site practices, such as grass swales and filter strips, can sometimes be implemented for relatively low cost.

There are exceptions to the general conclusion that larger-scale stormwater practices tend to be less costly on a per-unit basis than more numerous and distributed on-site practices. For instance, in Sun Valley, California, a recent study indicates that installing small distributed practices (infiltration practices, porous pavement, rain gardens) was more cost effective than centralized approaches for a retrofit program (Cutter et al., 2008). In this particular setting, the difference tended to revolve around the high land costs in the urbanized setting. Small-scale practices can be placed on low-valued land or integrated into existing landscaping, reducing land costs. Centralized stormwater facilities require substantial purchases of high-priced urban properties. Similarly, small distributed practices (porous pavement, green roofs, rain gardens, and constructed wetlands) can also provide a more cost-effective approach to reducing combined sewer overflow (CSO) discharges in a highly urban setting than large structural CSO controls (storage tanks) (Montalto et al., 2007).

SCMs are now a part of most development processes and consequently will increase the cost of the development. Randolph et al. (2006) report on the cost of complying with stormwater and sediment and erosion control regulations for six developments in the Washington, D.C., metropolitan area. These costs include primarily stormwater facility construction and land costs. The findings from these case studies indicate that stormwater and erosion and sediment control comprised about 60 percent of all environmental-related compliance costs for the residential developments studied and added about \$5,000 to the average price of a home. Nationwide, stormwater and erosion and sediment controls are estimated to add \$1,500 to \$9,000 to the cost of a new residential dwelling unit (Randolph et al., 2006).

As a means to control targeted chemical constituents, SCMs may be an expensive control option relative to other control alternatives. For example, nutrients from anthropogenic sources are an increasing water quality concern for many fresh and marine waters. Some states (e.g., Virginia, Maryland, and North Carolina) require stormwater programs to achieve specific nutrient (nitrogen or phosphorus) stormwater standards. The construction, maintenance, and land costs of reducing nitrogen discharge from residential developments using bioretention areas, wet ponds, constructed wetlands, or sand filters range from \$60 to \$2,500 per pound (Aultman, 2007). These control costs can be an order of magnitude higher than nitrogen control costs from point sources or agricultural nonpoint sources. The high per-pound removal costs are due in part to the relatively low mass load of nutrients carried in stormwater runoff. These estimates, however, assume that all costs are allocated exclusively to nitrogen removal. The high per-pound removal costs from the control of single pollutants highlight the importance of achieving ancillary and offsetting benefits associated with stormwater control (e.g., removal of other pollutants of concern, stream-channel protection from volume reduction, and enhancement of neighborhood amenities).

It should also be noted that installing SCMs in an existing built environment tends to be significantly more expensive than new construction. Construction costs for retrofitted extended detention ponds, wet ponds, and constructed wetlands were estimated to be two to seven times more costly than new SCMs (Schueler et al., 2007). Retrofit costs can be higher for a variety of reasons, including the need to upgrade existing infrastructure (culverts, drainage channels, etc.) to meet contemporary engineering and regulatory requirements. Retrofitting a single existing residential city block in Seattle with a new stormwater drainage system that included reduced street widths, biofiltration practices, and enhanced vegetation cost an estimated \$850,000 (see Box 5-5; Seattle Public Utilities, 2007). Estimates suggested that the costs might have been even

higher using more conventional stormwater piping/drainage systems (Chris May, personal communication, August 2007; EPA, 2007).

As discussed earlier in the chapter, stormwater runoff can be reduced and managed through better site design to reduce impervious cover. Low- to medium-density developments can reduce impervious cover through cluster development patterns that preserve open space and reduce lot sizes. Impervious surfaces and infiltration rates could be altered by any number of site-design characteristics such as reduction in street widths, reduction in the number of cul-de-sacs, and different setback requirements (CWP, 2000a). Finally, impervious surface per capita could be substantially reduced by increasing the population per dwelling unit.

Quantifying the cost of many of these design features is more challenging, and the literature is much less developed or conclusive than the literature on conventional SCM costs. Many design features described above (clustering, reduced setbacks, narrower streets, less curb and gutter) can significantly lower construction and infrastructure costs (CWP, 2001; EPA, 2007). Such features may reduce the capital cost of subdivision development by 10 to 33 percent (CWP, 2000a).

On the other hand, the evidence is unclear whether consumers are willing to pay for these design features. If consumers prefer features typically associated with conventional developments (large suburban lot, for example), then some aspects of alternative development designs/patterns could impose an opportunity cost on builders and buyers alike in the form of reduced housing value. For example, most statistical studies in the U.S. housing market find that consumers prefer homes with larger lots and are willing to pay premiums for homes located on cul-de-sacs, presumably for privacy and safety reasons (Dubin, 1998; Fina and Shabman, 1999; Song and Knapp, 2003). These effects, however, might be partly or completely offset by the higher value consumers might place on the proximity of open space to their homes (Palmquist, 1980; Cheshire and Sheppard, 1995; Qiu et al., 2006). Anecdotal evidence indicates that residents feel that Seattle's Street Edge Alternative program (the natural drainage system retrofit program that combines swales, bioretention and reduced impervious surfaces) increased their property values (City of Seattle, undated). Studies that have attempted to assess the net change in costs are limited, but some evidence suggests that the amenity values of lower-impact designs may match or outweigh the disamenities (Song and Knapp, 2003).

Incentives for Stormwater Management

The dominant policy approach to controlling effluent discharge under the Clean Water Act is through the application of technology-based effluent standards or the requirements to install particular technologies or practices. Some note that this general policy approach may not provide the regulated community with (1) incentives to invest in pollution prevention activities beyond what is required in the standard or with (2) sufficient opportunities or flexibility to lower overall compliance costs (Parikh et al., 2005).

A loosely grouped set of policies, called here "incentive-based,"¹ aim to create financial incentives to manage effluent or volume discharge. Such policies tend to be classified into two groups: price- and quantity-based mechanisms (Stavins, 2000; Parikh et al., 2005). Price-based mechanisms are created when government creates a charge (tax, fee, etc.) or subsidy (payment)

¹ These policies are sometimes called "market-based" policies, but that term will not be used here because many of the incentive-based policies discussed fail to contain features characteristic of a market system.

on an outcome that government wants to either discourage or encourage. Ideally, the price would be placed on a target outcome (effluents discharged, volume of water released, etc.) and not on the means to achieve that outcome end (such as a tax or subsidy to adopt specific technologies or practices).² Quantity-based policies require government to establish some binding limit or cap on an outcome (e.g., mass load of effluent, volume of runoff, etc.) for an identified group of dischargers, but then allow the regulated parties to “trade” responsibilities for meeting that limit or cap. The opportunity to trade creates the financial incentive. The trading concept is discussed in greater detail in Chapter 6, while this section focuses on price-based incentives.

Some stormwater utilities offer reductions in stormwater fees to landowners who voluntarily undertake activities to reduce runoff from their parcels (Doll and Lindsey, 1999; Keller, 2003). The reduction in tax obligations, called credits, can be interpreted as a financial subsidy or payment for implementing on-site runoff controls. Credit payments are typically made based on the volume of water detained. For example, as part of Portland, Oregon’s Clean River Rewards program, residents and commercial property owners can reduce their stormwater utility fee by as much as 35 percent by reducing stormwater runoff from existing developed properties (Portland Bureau of Environmental Services, 2008a). Residential and commercial property owners are given a number of ways to reduce runoff to receive this financial benefit. In addition, Portland has a downspout disconnection program that aims to reduce discharge into CSOs in targeted areas in the city. Property owners may be reimbursed up to \$53 per eligible downspout (Portland Bureau of Environmental Services, 2008b).

Alternatively, stormwater utilities could (where allowed) also use fee revenue to provide private incentives for stormwater control through a competitive bidding process. Such a bidding process (“reverse auction”) would request proposals for stormwater reduction projects and fund projects that reduce volume at the least cost. Proposed investments that can meet the program objectives at the lowest per unit cost would receive payments. Such a program creates private incentives to search for low-cost stormwater investments by creating a price for runoff volume reduction. The bidding program could also be used to identify cost-effective stormwater investments in areas targeted for enhanced levels of restoration. A bidding program has been proposed as a way to lower overall costs of a stormwater program in Southern California (Cutter et al., 2008). Revenue to fund such a competitive bid program could come from a variety of sources including stormwater utility fees or fees paid into an in lieu fee program.

Finally, impact fees on new developments can be structured in a way to create incentives to reduce stormwater runoff volumes. Charges based on runoff volume (or a surrogate measure like impervious surface) can provide an incentive for developers to reduce the volume of new runoff created.

² The literature on what level to set the price (tax or subsidy) is vast, complex, and controversial. Parikh et al. (2005) seem to wander into this debate (perhaps unwittingly) by making a distinction between taxes based on some optimality rule (marginal damage costs equal to marginal control costs) and those based on some other sort of decision rule. Without getting into the specifics of this debate here, this discussion will simply assert more generally that price-based incentive policies structure taxes and subsidies to induce desirable behavioral change (rather than simply to raise revenue).

CHALLENGES TO IMPLEMENTATION OF WATERSHED-BASED MANAGEMENT AND STORMWATER CONTROL MEASURES

The implementation of SCMs has seen variable success. Environmental awareness, threats to potable water sources or to habitat for threatened and endangered species, problems with combined sewer overflows, and other environmental factors have caused cities such as Portland, Oregon; Seattle, Washington; Chicago, Illinois; and Austin, Texas to aggressively pursue widespread implementation of a broad range of SCMs. In contrast, other cities have been slow to implement recommended practices, for many reasons. This is particularly true for nonstructural SCMs, despite their popularity among planners and regulators for the past two decades. A host of real and perceived concerns about individual nonstructural SCMs are often raised regarding development costs, market acceptance, fire safety, emergency access, traffic and parking congestion, basement seepage, pedestrian safety, backyard flooding, nuisance conditions, maintenance, and winter snow removal operations. While most of these concerns are unfounded, they contribute to a culture of inertia when it comes to code change (CWP, 1998a, 2000a). As a result, some nonstructural SCMs are discouraged or even prohibited by local development codes. Very few communities make the consideration of nonstructural practices a required element of stormwater plan review, nor do they require that they be considered early in the site layout and design process when their effectiveness would be maximized. Finally, many engineers and planners feel they can fully comply with existing stormwater criteria without resorting to nonstructural SCMs.

Cost Issues

There are numerous cost issues that have proven to be significant barriers to the use of innovative SCMs. Special construction techniques required for the proper design and function of SCMs, specially formulated manufactured soils, expensive subsurface vaults, and increased land area requirements as a result of increased stormwater storage requirements can significantly increase site development costs. For smaller projects in highly urbanized areas where land costs are high, there can be a disproportionately large expense to comply with stormwater regulations, causing developers to seek, and often receive, exemption from requirements.

Sediment removal and related maintenance activities required to ensure the proper ongoing functioning of SCMs are activities that are not a part of normal building maintenance. Data on maintenance costs of SCMs on privately owned facilities are limited, and management companies responsible for commercial and office building maintenance have yet to provide SCM maintenance as part of their services.

Additional costs are incurred when development review periods by public agencies get extended because of an increased level of design review required to evaluate the compliance of SCMs with city ordinances. Additional review increases development costs and extends the design process. Even with specialized training for city staff to evaluate SCM submittals, deviation from the most basic type of SCM design seems to require extended review and documentation.

Cost concerns are partly responsible for the markedly slow implementation of the stormwater program. The federal deadlines for permit coverage have long passed; in fact more than 14 years have lapsed for medium and large municipalities. A good part of the delay can be

explained by the resistance of states and local governments to the unknown cost burden. Cities contend that the permit requirements are unreasonable, expensive, and unrealistic to achieve. Many local government officials view some permit provisions such as LID or better site design as intrusion into the land-use authority of local governments.

As discussed in Chapter 2, the U.S. Congress provided no start-up or upgrade financial assistance, unlike what it did for municipally owned and operated wastewater treatment plants after the promulgation of the NPDES permit program under the Clean Water Act in 1972. Local governments have been reluctant to tax residents or create stormwater utilities. States like California and Michigan even have laws that require voter approval in order for local governments to assess new fees. Thus, to implement the NPDES stormwater program, states have had to largely rely on stormwater permit fees collected to support a skeletal to modest staff for program oversight. In Denver, and presumably in other cities, there is no reduction in stormwater fees when impervious area is reduced because of construction of on-site SCMs. This amounts to a disincentive to do the "right thing." Meanwhile, the overall federal budget for the NPDES program, including stormwater, has been declining.

Long-Term Maintenance of Stormwater Control Measures

One of the weakest parts of most stormwater management programs is the lack of information about, and funding to support, the long-term maintenance of SCMs. If SCMs are not inspected and maintained on a regular basis, the stormwater management program is likely to fail. This also negatively impacts the design process—if there is no inspection program and no accountability for maintenance, the designer has no incentive to build better, more maintenance-friendly SCMs. Finally, without an accurate assessment of the maintenance needs of an SCM, land owners and other responsible parties cannot anticipate their total costs over the lifetime of the device.

Almost all SCMs require active long-term maintenance in order to continue to provide volume and water quality benefits (Hoyt and Brown, 2005; Hunt and Lord, 2006b). Furthermore, a typical municipality may contain hundreds or thousands of individual SCMs within its jurisdiction. Thus, the long-term obligations for maintenance are considerable. For example, the annual maintenance cost of 100 medium-sized wet ponds (one-half acre to 2 acres) is estimated to be a quarter of a million dollars (Hunt and Lord, 2006c). Currently, the majority of municipal stormwater programs do not have adequate plans or resources in place for the long-term maintenance of SCMs (GAO, 2007).

A number of issues confront the long-term maintenance of SCMs. First, legal and financial responsibility for maintenance must be assigned. Historically stormwater ownership and responsibility have been poorly defined and implemented (Reese and Presler, 2005). If a party is an industrial facility that is required to obtain a permit, then responsibility for maintaining SCMs rests with the permittee. Other instances are more ambiguous. For residential developments, the responsibility for long-term maintenance could be assigned to the developer (e.g., establishing long-term financial accounts for maintenance), individual landowners, homeowners associations, or the municipality itself. Some cities, like Austin and Seattle, assume responsibility for long-term maintenance of SCMs in residential areas. Concerns over assigning responsibility to individual residential landowners or homeowners associations include insufficient technical and financial resources to conduct consistent maintenance and a

lack of inspection to require maintenance. A recent survey of municipal stormwater programs found that less than one-third perform regular maintenance on stormwater detention ponds or water quality SCMs in general residential areas (Reese and Presler, 2005). To ensure that adequate maintenance will occur, municipalities can require performance securities (performance bonds, escrow accounts, letter of credit, etc.) that ensure adequate funds are available for maintenance and repair in the event of failure to maintain the SCM by the responsible party.

An effective maintenance program also requires a system to inventory and track SCMs, inspection/monitoring, and enforcement against noncompliance. The large number of SCMs to track and manage creates management challenges. Municipal stormwater programs must administer their regulatory programs, perform inspection and enforcement activities, and maintain SCMs in public lands/rights-of-way and sometimes in residential areas. Municipal programs often do not have adequate staff to ensure that these maintenance responsibilities are adequately carried out. The lack of adequate staff for inspection and an inadequate system for prioritizing inspections have been repeatedly pointed out (Duke and Beswick, 1997; Duke, 2007; GAO, 2007).

Tracking and monitoring costs may also create disincentives for municipalities to adopt or encourage smaller-scale SCMs. For example, residential-scale rain gardens, porous driveways, rain barrels, and grass swales all have the potential to increase the cost and complexity of compliance monitoring because of the multitude of small infiltration devices that are located on private property as opposed to having fewer SCMs located in public rights-of-way or public lands. Small-scale distributed SCMs located on private property raise concerns of municipal willingness to inspect and enforce against noncompliance. Indeed, some municipalities have banned innovative SCMs like pervious pavement because the municipalities have no means to ensure their maintenance and continued operation.

Finally, there is concern that there is inadequate funding to maintain the growing number of SCMs on the landscape. The long-term funding obligation for maintenance has been difficult to assess (GAO, 2007), partly because many stormwater programs frequently do not have adequate accounting practices to define capital value and depreciation, maintenance, operation, or management programs (Reese and Presler, 2005). The problem is compounded because the long-term maintenance cost associated with various types of SCMs is not well understood. Additional research and information are needed on the costs of maintaining the performance of SCMs as experienced in the field (rather than ex ante estimates based on design plans). Research into long-term maintenance costs should include not only routine operation and maintenance costs but also costs for inspection and enforcement and remediation costs associated with SCM performance failures. Such research is critical to understanding the long-term cost obligation that is being assumed by municipal stormwater programs that are responsible for managing a growing number of SCMs.

At the present time, the maintenance schedule for many of the proprietary and non-proprietary SCMs is poorly defined. It will vary with the type of drainage area and the activities that are occurring within it and with the efficiency of the SCM. (For example, the city of Austin, Texas, has determined that the average lifespan of their sand filters ranges from 5 to 15 years, but can be as little as one year if there is construction in the drainage area.) In order to establish a maintenance schedule, an assessment protocol needs to be adopted by municipalities. The protocol, which is specific to the type of SCM, could consist of the following: each year municipalities would be required to collect data from a subset of their SCMs on public and private property, and then over a period of years these data could be used to determine

maintenance schedules, predict performance based on age and sediment loading, and identify failed systems. A measurement of the depth of deposited sediment might be the only test needed for settling devices, such as hydrodynamic devices and wet detention ponds. Two levels of analysis could be performed for infiltration devices—one based on simple visual observations and the other using an instrument to check infiltration rates. These assessment methods for infiltration devices have been tested at the University of Minnesota (Gulliver and Anderson, 2007). Without an assessment protocol for SCMs, the chances for poor maintenance and outright failure are greatly increased, it is difficult if not impossible to determine the actual performance of an SCM, and there will be insufficient data to reduce the uncertainty in future SCM design.

Lack of Design Guidance on Important SCMs and Lack of Training

Progress in implementing SCMs is often handicapped by the lack of local or national design guidance on important SCMs, and by the lack of training among the many players in the land development community (planners, designers, plan reviewers, public works staff, regulators, and contractors) on how to properly implement them on the ground. For example, design guidance is lacking or just emerging for many of the non-traditional SCMs, such as conservation of natural areas, earthwork minimization, product substitution, reforestation, soil restoration, impervious cover reduction, municipal housekeeping, stormwater education, and residential stewardship. Some LID techniques are better covered, such as the standards for pervious concrete from the American Concrete Institute and the National Ready Mixed Concrete Association. Design guidance for traditional SCMs such as erosion and sediment control may exist but is often incomplete, outdated, or lacking key implementation details to ensure proper on-the-ground implementation. In other cases, design guidance is available, but has not been disseminated to the full population of Phase II MS4 communities. For example, in an unpublished survey of state manuals used to develop national post-construction stormwater guidance, Hirschman and Kosco (2008) found that less than 25 percent provided sizing criteria, detailed engineering design specifications, or maintenance criteria. Nationwide guidance on SCM design and implementation may not be advisable or applicable to all physiographic, climatic, and ecoregions of the country. Rather, EPA and the states should encourage the development of regional design guidance that can be readily adapted and adopted by municipal and industrial permittees. Improvement of SCM design guidance should incorporate more direct consideration of the parameters of concern, how they move across the landscape, and the issues in receiving waters—a strategy both espoused in this report (page 351) and in recent publications on this topic (Strecker et al., 2005, 2007).

The second key issue relates to how to train and possibly certify the hundreds of thousands of individuals that are responsible for land development and stormwater infrastructure at the local and state level. New stormwater methods and practices cannot be effectively implemented until local planners, engineers, and landscape architects fully understand them and are confident on how to apply them to real-world sites. Currently, stormwater design is not a major component of the already crowded curriculum of undergraduate or graduate planning engineering or landscape architecture programs. Most stormwater professionals acquire their skills on the job. Given the rapid development of new stormwater technologies, there is a critical need for implementation of regional or statewide training programs to ensure that stormwater

professionals are equipped with the latest knowledge and skills. The training programs should ultimately lead to formal certification for stormwater designers, inspectors, and plan reviewers.

Different Standards in Different Jurisdictions That Are Within the Same Watershed

Governmental and watershed boundaries rarely coincide, with the result that most watersheds are made up of many municipal bodies regulating stormwater management. Unfortunately in most cases there is no overarching stormwater regulatory structure that is based upon a watershed analysis. This can result in many unfortunate conflicts, where approval of a stormwater facility does not affect the community issuing the permit. It is often said that the most effective stormwater management for an area high in the watershed is to speed the water downstream, thus saving the upstream community but severely damaging the downstream rivers. While this may be an exaggeration, the problems downstream are less of a concern to the upper watershed communities, and downstream communities may not be able to solve their water issues without help from the upstream communities.

Often neighboring communities' plans or the methods or data used do not coincide. For example, often out-of-date rainfall distributions, methods, or standards are required in the code that do not apply to the newer focus on smaller storms and volume reduction. If methods that include Modified Rational or TR-55 are used, it is difficult if not impossible to show the benefits in peak flow reduction gained through volume reduction devices. Also, some municipalities may require curb and piping and not allow swales, impeding the implementation of a cost-effective design. Finally, it is difficult to observe a measureable impact of SCMs when they are guided by a patchwork of regulations. One community may require removal of the first inch of runoff, and another may require the reduction of the 25-year, post-construction peak to the 10-year pre-construction level.

Water Rights that Conflict with Stormwater Management

In the West, water is considered real property, governed by state law and regional water compacts. Landowners in urban areas rarely own surface water rights and are typically prohibited from "beneficial use" of that water, which affects how SCMs are chosen. For example, current practices in Colorado typically allow stormwater to be infiltrated within a short period of time on-site without violation of water laws. However, storage of and/or pumping this water for broader distribution is considered to be a beneficial use and is therefore prohibited. Moreover, as discussed in Chapter 2, SCMs that manage stormwater by driving the water underground with a bored, drilled, or driven shaft or a hole dug deeper than its widest surface dimension are typically considered to be "injection wells," requiring a federal permit and regular monitoring under the Safe Drinking Water Act.

Some states prohibit infiltration because of concerns over long-term groundwater pollution. In California, which does not have a uniform policy for groundwater management and groundwater rights, authority over groundwater quality management falls to several regional and local agencies. For example, the Upper Los Angeles River Area (ULARA) has a court-appointed Watermaster to manage the complex appropriation of its groundwater to user cities and agencies. The ULARA has clashed with the City of Los Angeles regarding rights to all of

the water that normally recharges the Los Angeles River via runoff from precipitation. In 2000, the ULARA Watermaster expressed a concern with certain permit provisions of the Los Angeles County MS4 Permit for New Development/ Redevelopment that promoted infiltration, stating that the MS4 permit interfered with the adjudicated right of the City of Los Angeles to manage groundwater.

Urban Development and Sprawl

The continued expansion of urban areas is inevitable given population increases worldwide and the transition from agricultural to industrial economies. Given that urbanization of almost any magnitude—even less than 10 percent impervious area—has been demonstrated to have an impact on in-stream water quality, a central question to be addressed is how water quality can be maintained as cities grow, without having negative impacts on social and economic systems. Ideally, SCMs would perform their water quality function, contribute to the livability of cities, and enhance their economic and social potentials.

Low-density, auto-oriented urban development, commonly known as sprawl, has been the predominant pattern of development in the United States, and increasingly worldwide, since World War II. It has been widely criticized for its inefficient use of land, its high use of natural resources, and its high energy costs—all of which are associated with the required auto-oriented travel. Additionally, ongoing economic costs related to the provision of widely dispersed services and social impacts of a breakdown in community life have been identified (Brugemann, 1974). Sprawl and the impacts on in-stream water quality that result from urbanization have been an inevitable consequence of improved economic conditions. In the United States, sprawl constitutes the vast majority of development occurring today because a majority of the population is attracted to the benefits of a suburban lifestyle, government has subsidized roads and highways at the expense of public transit, and local zoning often limits development density.

There has been a great deal of innovation in city planning and design in the past decade that encourages greater density and a return to urban living. New types of zoning, New Urbanism, Smart Growth, and related innovations in urban planning and design have been developed in parallel with environmental regulations at local to national levels (see Chapter 2). They acknowledge the importance of protecting natural resources to maintain quality of life and have established water quality as an important consideration in city building.

It is not clear that current stormwater regulations can be effectively implemented over the broad range of development patterns that characterize contemporary cities or if they inadvertently favor one type of development over another. For example, on-site SMCs are often recommended as the preferred means of stormwater management, although they tend to encourage lower-density development patterns. And while they are easily implemented and regulated given the incremental, site-by-site development that is typical of most urban growth, monitoring and maintenance can be expensive and difficult for both the individual property owner and the regulating authority. In highly urbanized areas, they are often relegated to subsurface systems that are expensive and that, to be effective, require high levels of maintenance.

In newly developing areas, cluster development should be encouraged whenever possible, according to the Smart Growth principles of narrower streets, reduced setbacks, and related approaches to reduce the amount of impervious area required and land consumed. Furthermore,

an interconnected series of on-site and consolidated SCMs can reduce subsurface stormwater piping requirements. Most planned communities have dedicated park and open-space areas that can constitute 25 percent or more of a development's total land area, making it feasible to easily accommodate consolidated SCMs (typically 8 to 10 percent of impervious area) within multi-functional open space and park lands. Cost efficiencies such as a 30 percent reduction in infrastructure costs (Duaney Plater-Zyberk & Company, 2006) can be realized through Smart Growth development techniques. Clustered housing surrounded by open space, laced with trails, has appreciated in value at a higher rate than conventionally designed subdivisions (Crompton, 2007).

In order to encourage infill or redevelopment over sprawl patterns of development, innovative zoning and other practices will be needed to prevent stormwater management from becoming onerous. For example, incentive zoning or performance zoning could be used to allow for greater densities on a site, freeing other portions of the site for SCMs. Innovations in governance and finance can also be used to incorporate consolidated SCMs into urban environments. For example, the City of Denver, in updating its Comprehensive Plan, designated certain underdeveloped corridors and districts in the city as "areas of change" where it hoped to encourage large-scale infill redevelopment. Given the scale of redevelopment, it would be feasible to establish special maintenance districts, allowing the development of consolidated SCMs that have multiple functions. To fund land purchase and facility design and construction, cash in lieu of payments could be made.

Safety and Aesthetic Concerns

Vector-borne diseases, especially West Nile virus, are a concern when SCMs such as extended detention basins, constructed wetlands, and rain barrels are proposed. Furthermore, other SCMs that are poorly designed, improperly constructed, or inadequately maintained may retain water and provide an ideal breeding ground for mosquitoes, increasing the potential for disease transmission to humans and wildlife. Kwan et al. (2005) found that water-retaining SCMs increase the availability of breeding habitats for disease vectors and provide opportunistic species an extended breeding season. State Health Departments generally recommend that SCMs be designed to drain fully in 72 hours, which is the minimum time required for a mosquito to complete its life cycle under optimum conditions. In SCMs where there is permanent standing water, such as stormwater wetlands, there is the possibility of introducing biota that might prey on mosquitoes. Municipalities may have to consider the added cost of vector control and public health when implementing stormwater quality management programs.

With larger consolidated and regional extended detention facilities, concerns about the safety of children who may be attracted to such SCMs and ensuing liability must be considered. These SCMs need to be fenced off or otherwise designed appropriately to reduce the risk of drowning.

One aspect of stormwater management that is infrequently considered is the aesthetic appeal, or lack thereof, of SCMs. The visual qualities of SCMs are important because they are a growing part of the urban landscape setting. Although it can be assumed that landscapes that are carefully tended are often preferred over other types of landscapes, it depends substantially on one's point of view. For example, an engineer may consider a particular SCM that is functioning as expected to be beautiful in the sense that its engineering function has been realized, even

though there is sediment buildup, algae, or other products of a properly functioning SCM visible. Similarly, a biologist or ecologist evaluating an ecologically healthy SCM in an urban context might find it to be beautiful because of its biological or ecological diversity, whereas another individual who evaluates the same SCM finds it to be "weedy." SCMs can be viewed as a means of restoring a degraded landscape to a state that might have existed before urban development. The desire to "return to nature" is a seductive idea that suggests naturalistic SCMs that may have very little to do with an original landscape, given the dramatic changes in hydrology that are inevitable with urban streams. Each of these widely varied views of SCMs may be appropriate depending on the context and the viewer.

One goal of stormwater management should be to make SCMs desirable and attractive to a broader audience, thereby increasing their potential for long-term effectiveness. For example, the Portland convention center rain gardens demonstrate how native and non-native wetland plantings can be carefully composed as a landscape composition and also provide for stormwater treatment. If context and aesthetics of a chosen SCM are poorly matched, there is a high probability that the SCM will be eliminated or its function compromised because of modifications that make its landscape qualities more appropriate for its context.

CONCLUSIONS AND RECOMMENDATIONS

SCMs, when designed, constructed, and maintained correctly, have demonstrated the ability to reduce runoff volume and peak flows and to remove pollutants. However, in very few cases has the performance of SCMs been mechanistically linked to the guaranteed sustainment at the watershed level of receiving water quality, in-stream habitat, or stream geomorphology. Many studies demonstrate that degradation in rivers is directly related to impervious surfaces in the contributing watershed, and it is clear that SCMs, particularly combinations of SMCs, can reduce the runoff volume, erosive flows, and pollutant loadings coming from such surfaces. However, none of these measures perfectly mimic natural conditions, such that the accumulation of these SCMs in a watershed may not protect the most sensitive beneficial aquatic life uses in a state. Furthermore, the implementation of SCMs at the watershed scale has been too inconsistent and too recent to observe an actual cause-and-effect relationship between SCMs and receiving waters. The following specific conclusions and recommendations about stormwater control measures are made.

Individual controls on stormwater discharges are inadequate as the sole solution to stormwater in urban watersheds. SCM implementation needs to be designed as a system, integrating structural and nonstructural SCMs and incorporating watershed goals, site characteristics, development land use, construction erosion and sedimentation controls, aesthetics, monitoring, and maintenance. Stormwater cannot be adequately managed on a piecemeal basis due to the complexity of both the hydrologic and pollutant processes and their effect on habitat and stream quality. Past practices of designing detention basins on a site-by-site basis have been ineffective at protecting water quality in receiving waters and only partially effective in meeting flood control requirements.

Nonstructural SCMs such as product substitution, better site design, downspout disconnection, conservation of natural areas, and watershed and land-use planning can dramatically reduce the volume of runoff and pollutant load from a new development.

Such SCMs should be considered first before structural practices. For example, lead concentrations in stormwater have been reduced by at least a factor of 4 after the removal of lead from gasoline. Not creating impervious surfaces or removing a contaminant from the runoff stream simplifies and reduces the reliance on structural SCMs.

SCMs that harvest, infiltrate, and evapotranspire stormwater are critical to reducing the volume and pollutant loading of small storms. Urban municipal separate stormwater conveyance systems have been designed for flood control to protect life and property from extreme rainfall events, but they have generally failed to address the more frequent rain events (<2.5 cm) that are key to recharge and baseflow in most areas. These small storms may only generate runoff from paved areas and transport the “first flush” of contaminants. SCMs designed to remove this class of storms from surface runoff (runoff-volume-reduction SCMs—rainwater harvesting, vegetated, and subsurface) can also address larger watershed flooding issues.

Performance characteristics are starting to be established for most structural and some nonstructural SCMs, but additional research is needed on the relevant hydrologic and water quality processes within SCMs across different climates and soil conditions. Typical data such as long-term load reduction efficiencies and pollutant effluent concentrations can be found in the International Stormwater BMP Database. However, understanding the processes involved in each SCM is in its infancy, making modeling of these SCMs difficult. Seasonal differences, the time between storms, and other factors all affect pollutant loadings emanating from SCMs. Research is needed that moves away from the use of percent removal and toward better simulation of SCM performance. Hydrologic models of SCMs that incorporate soil physics (moisture, wetting fronts) and groundwater processes are only now becoming available. Research is particularly important for nonstructural SCMs, which in many cases are more effective, have longer life spans, and require less maintenance than structural SCMs. EPA should be a leader in SCM research, both directly by improving its internal modeling efforts and by funding state efforts to monitor and report back on the success of SCMs in the field.

Research is needed to determine the effectiveness of suites of SCMs at the watershed scale. In parallel with learning more about how to quantify the unit processes of both structural and nonstructural practices, research is needed to develop surrogates or guidelines for modeling SCMs in lumped watershed models. Design formulas and criteria for the most commonly used SCMs, such as wet ponds and grass swales, are based on extensive laboratory and/or field testing. There are limited data for other SCMs, such as bioretention and proprietary filters. Whereas it is important to continue to do rigorous evaluations of individual SCMs, there is also a role for more simple methods to gain an approximate idea about how SCMs are performing. The scale factor is a problem for watershed managers and modelers, and there is a need to provide guidance on how to simulate a watershed of SCMs, without modeling thousands of individual sites.

Improved guidance for the design and selection of SMCs is needed to improve their implementation. Progress in implementing SCMs is often handicapped by the lack of design guidance, particularly for many of the non-traditional SCMs. Existing design guidance is often

incomplete, outdated, or lacking key details to ensure proper on-the-ground implementation. In other cases, SCM design guidance has not been disseminated to the full population of MS4 communities. Nationwide guidance on SCM design and implementation may not be advisable or applicable to all physiographic, climatic, and ecoregions of the country. Rather, EPA and the states should encourage the development of regional design guidance that can be readily adapted and adopted by municipal and industrial permittees. As our understanding of the relevant hydrologic, environmental, and biological processes increases, SCM design guidance should be improved to incorporate more direct consideration of the parameters of concern, how they move across the landscape, and the issues in receiving waters.

The retrofitting of urban areas presents both unique opportunities and challenges.

Promoting growth in these areas is desirable because it takes pressure off the suburban fringes, thereby preventing sprawl, and it minimizes the creation of new impervious surfaces. However, it is more expensive than Greenfields development because of the existence of infrastructure and the limited availability of land. Both innovative zoning and development incentives, along with the selection of SCMs that work well in the urban setting, are needed to achieve fair and effective stormwater management in these areas. For example, incentive or performance zoning could be used to allow for greater densities on a site, freeing other portions of the site for SCMs. Publicly owned, consolidated SCMs should be strongly considered as there may be insufficient land to have small, on-site systems. The performance and maintenance of the former can be overseen more effectively by a local government entity. The types of SCMs that are used in consolidated facilities—particularly detention basins, wet/dry ponds, and stormwater wetlands—perform multiple functions, such as prevention of streambank erosion, flood control, and large-scale habitat provision.

FINDINGS OF FACT, CONCLUSIONS
OF LAW, AND ORDER

PHASE I

PCHB NOS. 07-021, 07-026, 07-027
07-028, 07-029, 0-030,
07-037

These consolidated appeals involve the regulation of stormwater discharges from municipal storm sewer systems under a National Pollutant Discharge Elimination System (NPDES) and State Waste Discharge General Permit (State Waste Permit). In these appeals, multiple parties challenge the validity of the Department of Ecology's (Ecology) 2007 Phase I Municipal Stormwater General Permit (Phase I Permit). This permit was issued pursuant to the

1 Federal Water Pollution Control Act, commonly known as the "Clean Water Act" (CWA), 33
2 U.S.C. § 1251 *et seq.* and the state Water Pollution Control Act, (WPCA), Chapter 90.48 RCW.

3 The Pollution Control Hearings Board (Board) held a multiple day hearing between April
4 29, 2008 and May 8, 2008. Attorneys Todd True and Jan Hasselman represented Appellants
5 Puget Soundkeeper Alliance and People for Puget Sound (PSA). Attorney Tad H. Shimazu
6 represented Appellant Pierce County. Assistant City Attorney Doug Mosich represented
7 Appellant City of Tacoma. Attorneys Susan Ridgley and Tanya Barnett represented Appellant
8 Port of Seattle. Catherine A. Drews and Elizabeth E. Anderson, Deputy Prosecuting Attorneys,
9 represented Appellant Snohomish County. E. Bronson Potter, Senior Deputy Prosecuting
10 Attorney and Rodney Swanson, Clark County Department of Public Works represented
11 Appellant Clark County. Attorneys Loren R. Dunn and Blake Mark-Dias represented Appellants
12 Pacificorp and Puget Sound Energy (Utilities). Ronald L. Lavigne, Senior Counsel, and Thomas
13 J. Young, Assistant Attorney General represented Respondent Ecology. Assistant City Attorney
14 Theresa R. Wagner represented Intervenor City of Seattle. Senior Deputy Prosecuting Attorney
15 Joseph B. Rochelle and Deputy Prosecutor Verna P. Bromley represented Intervenor King
16 County. Attorney Carolyn Lake represented Intervenor Port of Tacoma. Stephen Klasinski,
17 Assistant Attorney General represented Intervenor Washington State Department of
18 Transportation (WSDOT).

19 Chair, Kathleen D. Mix, William H. Lynch, and Andrea McNamara Doyle comprised the
20 Board. Administrative Appeals Judge Kay M. Brown, presided for the Board. Randi Hamilton
21

1 and Kim L. Otis of Gene Barker and Associates of Olympia, Washington provided court
2 reporting services.

3
4 PROCEDURAL BACKGROUND

5 On January 17, 2007, Ecology issued the Phase I Permit for discharges from large and
6 medium municipal separate storm sewer systems (called MS4s). The Phase I Permit went into
7 effect on February 16, 2007.

8 PSA, Pierce County, City of Tacoma, Port of Seattle, Snohomish County, Clark County,
9 and the Utilities appealed the Phase I Permit.¹ The Board conducted pre-hearing conferences,
10 and entered pre-hearing orders for the Phase I Appeal. The parties raised multiple issues. The
11 Board addressed many of these issues in a separate summary judgment order² and has resolved
12 others through orders on summary judgment and after a hearing on the merits related to the
13 Permit's Special Condition S4.³ The parties also withdrew some of the issues. This decision
14 resolves the remaining issues, which include the following:⁴

15 C. Special Condition 8 re: Monitoring (challenged only by Clark and Pierce
16 County)⁵

17 ¹ City of Pacific (PCHB No. 07-031), Whatcom County (PCHB No. 07-032), and Sammamish Plateau Water &
18 Sewer District (PCHB No. 07-024) filed additional appeals, but they are not part of this consolidated action.

² See Order on Dispositive Motions (Phase I Municipal Stormwater Permit), issued on April 7, 2008.

³ See Order on Dispositive Motions: Condition S4, issued on April 2, 2008 and Findings of Fact, Conclusions of
19 Law and Order, Condition S4, issued on August 7, 2008.

⁴ The numbering of these issues was retained from the numbering system used in the Third Pre-Hearing Order
20 issued on December 11, 2007.

⁵ All of the permittee appellants initially raised issues related to the S8 monitoring provisions. These issues were
21 resolved through an agreement between Ecology and all of the permittee appellants except Clark and Pierce County.
See Ex. Ecy 11 (Phase I). The agreement also resolves issues raised by Snohomish County related to Special
Condition S7.

- 1 1. Whether the requirements imposed in Special Condition S8 are lawful,
2 practicable, reasonable, and/or designed to achieve the goals of the statutory
municipal stormwater permit program?
- 3 3. Whether the monitoring requirements imposed in Special Condition S8 are
4 overly broad, overly prescriptive, and cost-ineffective so that requiring
5 implementation of such requirements as written is unlawful, impracticable,
6 and/or unreasonable?
- 7 E. Issues Specific to the Ports of Seattle and Tacoma
- 8 5. Whether the requirement in Special Condition S6.E.7 to prepare and
9 implement SWPPP(s) for "all Port-owned lands," regardless of their capacity
10 to generate pollutants or other site-specific characteristics, is unlawful,
11 unreasonable, unjust, or invalid?
- 12 F. Joint Environmental Legal Issues
- 13 1. Low-Impact Development:
- 14 a. Does the permit fail to require maximum on site dispersion and
15 infiltration of stormwater, through the use of "low impact
16 development" techniques, basin planning, and other appropriate
17 technologies, and if so, does that failure unlawfully cause or contribute
18 to violations of water quality standards?
- 19 b. Does the permit fail to require maximum onsite dispersion and
20 infiltration of stormwater, through the use of "low impact
21 development" techniques, basin planning, and other appropriate
technologies, and if so, does that failure unlawfully allow permittees to
discharge pollutants that have not been treated with all known
available and reasonable methods of treatment ("AKART"), and/or fail
to reduce the discharge of pollutants to the maximum extent
practicable ("MEP")?
2. Existing Development:
- a. Does the absence of any standard and/or technology requirements for
reducing stormwater discharges from existing development and
existing stormwater systems unlawfully cause or contribute to
violations of water quality standards?

1

9
10
11
12
13
14
15
16
17
18
19
20
21

b. Does the absence of any standard and/or technology requirements for reducing stormwater discharges from existing development and existing stormwater systems unlawfully allow permittees to discharge pollutants that have not been treated with AKART, and/or fail to reduce the discharge of pollutants to MEP?

3. Monitoring: Is the monitoring required under Permit Condition S.8 unlawful because it is inadequate to determine whether: (i) the permittee is in compliance with water quality standards; (ii) discharges are causing or contributing to violations of water quality standards; or (iii) discharges are being treated with AKART and/or MEP?⁶

4. Water Quality Standards Violations:

a. Does the Phase I permit fail to ensure that discharges will not cause or contribute to violations of water quality standards?⁷

5. Compliance:

a. Does the permit unlawfully provide for compliance with permit terms on a schedule that is indefinite and unenforceable, not as expeditious as possible, and/or in excess of statutory deadlines?

b. Does the permit unlawfully allow a permittee to create and implement permit requirements without Ecology's oversight or involvement?

Based on pre-filed testimony, multiple days of sworn testimony of witnesses, extensive exhibits submitted into the record, and argument from counsel representing the numerous parties that participated in these consolidated appeals, and having fully considered the record, the Board enters the following decision:

⁶ PSA is not challenging the monitoring provisions of the permit. This issue is brought by the Utilities only.

⁷ This issue also includes the issue originally stated as S4.6: Does the prohibition on violations of water quality standards contained in Permit Condition S4 unlawfully or unreasonably conflict with the other provisions of the permit?

1 SUMMARY OF THE DECISION

2 The Board concludes that the monitoring program established in Special Condition S8
3 and required of all permittees is a valid exercise of Ecology's technical expertise and discretion.
4 (Issues C.1 and 3, and F.5). The Board upholds the permit term requiring that Stormwater
5 Pollution Prevention Plans (SWPPPs) be prepared on all port-owned lands, but directs that
6 Ecology modify the condition to exempt environmental mitigation sites owned by the Port of
7 Tacoma from the SWPPP preparation requirement. (Issue E.5). The Board concludes that the
8 Phase I Permit fails to require that the municipalities control stormwater discharges to the
9 maximum extent practicable, and does not require application of all known, available, and
10 reasonable methods to prevent and control pollution, because it fails to require more extensive
11 use of low impact development (LID) techniques. (Issue F.1.b). To remedy this problem, the
12 Board directs Ecology to make specific changes to some provisions in the permit, and also
13 remands the permit with direction to Ecology to require the permittees to develop methods for
14 use of low impact development at parcel and subdivision levels in their jurisdictions. The Board
15 concludes that permittees must provide information in their annual report to Ecology on the
16 extent to which basin planning is being undertaken or should be considered in their jurisdiction
17 in order to assist with future phases of the permit. The areas identified should be relatively
18 undeveloped where new development is occurring, and from which discharges may impact
19 aquatic resources. The Board concludes that the structural stormwater control program
20 provisions of the permit, as drafted, constitute impermissible self regulation. (Issues F.2 and
21 F.5.b). To remedy this deficiency, the Board directs modification of the permit to require

1 permittees to describe the prioritization of their selected structural control projects. The Board
2 ~~affirms the source control program requirements without change. Finally, the Board concludes~~
3 that PSA and the Utilities failed to prove that any of the conditions of the permit violate the
4 timing requirements of 33 U.S.C. § 1342 (p)(4)(A) (Issue F.5.a).

5 FINDINGS OF FACT

6 A. History of Phase I Permit

7 1.

8 Ecology developed the current Phase I Permit through an eight year long process. The
9 2007 Phase I Permit replaced the first municipal stormwater NPDES and State Waste Permits,
10 which were issued in 1995 and expired in July of 2000. *Testimony of Wessel, Moore, Exs. Muni*
11 *0002, p. 17, 0006, 0007, 0008, 0009.*

12 2.

13 On January 19, 1999, Ecology filed a Notice of Intent to reissue the 1995 permits. *Ex.*
14 *Muni 0002, p. 6.* Ecology formed an advisory committee, which included representatives from
15 cities, counties, state and federal agencies, environmental groups, and the public, to assist with
16 development of the revised permit. This committee met several times during 1999 and 2000.
17 *Testimony of Wessel, Moore, Exs. Muni 0002, p. 6-7.* The 1995 Phase I Permit closely followed
18 the EPA Phase I Regulations, which allowed the permittees to propose what was contained
19 within their own stormwater programs. Ecology was dissatisfied with this approach and decided
20 that more detailed requirements were needed for the 2007 Phase I Permit. *Testimony of Moore.*

12

13

14

15

16

17

18

19

20

21

~~Completion of the new permit was delayed at several junctures as a result of a number of~~

intervening events and shifting priorities, including the federal listing of Puget Sound Chinook Salmon in 1999, the adoption of EPA's Phase II rules, and Ecology's decision to revise the state's Stormwater Management Manuals and develop the first Phase II municipal stormwater permits in tandem with the Phase I permit update. *Testimony of Wessel, Moore, Exs. ECY 6 (Phase I), Muni 0002, p. 7.*

4.

In response to legislative interest in the new federal requirements for municipal stormwater permits, Ecology convened two advisory groups during the summer of 2003: one for Eastern Washington and one for Western Washington. Each advisory group submitted a report of its findings to Ecology in early December, 2003. Ecology developed its own recommendations and published these, together with the recommendations from both advisory groups, in a report to the Legislature dated January, 2004. *Testimony of Moore, Exs. ECY 6 (Phase I), Muni 0002, p. 7.*

5.

Ecology filed a notice of intent to issue the Phase I and Phase II Permits in June of 2004. The agency released the first preliminary draft of the Phase I Permit for public comment in May, 2005, and the first formal draft in February, 2006. *Exs. PSA 018, Muni-0100.* Ecology received and reviewed thousands of pages of public comment, and responded to those comments in a 205 page document when it released the revised, final permit in January, 2007. *Exs. Muni 002, p. 7-*

1 8, *ECY 3 (Phase I)*. Ecology issued the Phase I permit, in its current form, on January 17, 2007.

2 ~~It became effective on February 16, 2007, and expires on February 15, 2012. Ex. Muni 001,~~

3 *Testimony of Moore.*

4 B. Overview of the permit

5 6.

6 The Phase I Permit regulates discharges from municipal separate storm sewer systems
7 (MS4s) owned or operated by the following large and medium municipalities statewide: City of
8 Seattle, City of Tacoma, Clark County, King County,⁸ Pierce County and Snohomish County.⁹ It
9 also allows coverage of "secondary permittees," including the Ports of Seattle and Tacoma, for
10 discharges from other publicly owned or operated municipal separate sewer systems located
11 within the primary permittee cities and counties. Secondary permittees as a group are subject to
12 somewhat different terms under the permit than primary permittees, and the permit also has
13 specific terms applicable only to the Ports of Seattle and Tacoma and not other secondary
14 permittees. The Phase I permit does not cover direct discharges into waters of the state from
15 privately owned stormwater systems, nor does it cover the storm sewers owned and operated by
16 the Washington State Department of Transportation (WSDOT).¹⁰ Unlike traditional NPDES
17 permits, the Phase I permit is a "programmatic permit," meaning it requires the municipal

18 ⁸ King County Department of Metropolitan Services (METRO) is covered as a "co-permittee" with the City of
19 Seattle for discharges from outfalls King County owns or operates in the City of Seattle. *Special Condition S1.C.,*
Exs. Muni 0001, p. 1, Muni 0002, p. 21.

20 ⁹ An MS4 consists of all of the conveyances, or systems of conveyances (including roads with drainage systems,
21 municipal streets, catch basins, curbs gutters, ditches manmade channels or storm drains) designed or used for
collecting or conveying stormwater. By definition, these systems cannot be combined with sanitary sewer systems.
Exs. Muni 0001, p. 61, 63, Muni 0002, p. 22-24.

¹⁰ The Phase I permit does not cover the storm sewers owned and operated by the Washington State Department of
Transportation (WSDOT). WSDOT's system is covered under an individual permit. *Ex. Muni 0002, p. 19, 21.*

1 permittees to implement area-wide stormwater management programs rather than establishing
2 ~~benchmarks or other numeric or narrative effluent limits for stormwater discharges from~~
3 individual outfalls. *Testimony of Moore, Exs. Muni 0001, p. 1, 2, 60-65, Muni 0002, p 20-24.*

4 7.

5 The heart of the Phase I Permit requires that permittees implement a Stormwater
6 Management Program (SWMP). Special Condition S5 contains the SWMP requirements for the
7 primary permittees, and Special Condition S6 sets out the SWMP requirements for secondary
8 and co-permittees. The required elements of the SWMP track closely with EPA's Part II
9 Application rules but contain much more detailed minimum performance standards for the
10 municipalities' programs. This approach avoids the need for separate review and approval by
11 Ecology of each SWMP prior to coverage under the Phase I Permit. Instead, a permittee is
12 required to submit the SWMP with the permittee's first year annual report. S5.A. *Testimony of*
13 *Moore, Wessel; Exs. Muni 0001, p. 6-25; Muni 0002, p. 18, 28-42.*

14 8.

15 Ecology views these SWMP requirements, in the aggregate, to represent the MEP
16 standard; that is, permittees who implement all of the program requirements in combination with
17 one another are considered by Ecology to be reducing the discharge of pollutants to the
18 maximum extent practicable, even though it may be possible for a permittee to do more in a
19 specific program element or at a specific outfall if the individual requirements were evaluated in
20 isolation from the rest of the program requirements. *Testimony of Moore.*

21

16
17
18
19
20
21

9.

Under Special Condition S5 the SWMP must include ten component parts, which are mandatory to the extent allowable under state and federal law. These program components address the following topics, and the minimum requirements for each are set out in S5.C. 1 through 10 of the Phase I Permit: (1) Legal authority; (2) System mapping and documentation; (3) Coordination; (4) Public involvement; (5) Controlling runoff from new development, redevelopment, and construction; (6) Structural stormwater controls (retrofits); (7) Source control for existing development; (8) Illicit connections, illicit discharge detection and elimination; (9) Operations and maintenance; and (10) Education and outreach. *Muni 0001, p. 6-25.*

10.

More specifically, S5.C.1 requires the permittee to demonstrate by the effective date of the Phase I Permit that it has the legal authority to control discharges to and from its MS4s. S5.C.2 requires the permittee to map, by specific dates, prescribed parts of its MS4. S5.C.3 requires the permittee to establish coordination mechanisms to remove barriers to stormwater management created by the need to coordinate efforts both internally within one governmental entity, and externally with jurisdictions that share drainage basins. S5.C.4 requires the permittee to provide ongoing opportunities for public involvement in its stormwater management program. S5.C.5 requires the permittee to develop a program to prevent and control impacts of runoff from new development, redevelopment, and construction activities. S5.C.6 requires the permittee to

1 include a program to construct structural stormwater controls to prevent or reduce impacts from
2 ~~discharges from its MS4s. This element is applicable to existing development, as well as new~~
3 development, and addresses impacts that are not already adequately controlled by other required
4 actions under the SWMP. S5.C.7 requires the permittee to include a source control program for
5 existing development that reduces pollutants in runoff from these areas. S5.C.8 requires the
6 permittee to have an ongoing program to detect, remove and prevent illicit connections and illicit
7 discharges, including spills, into its MS4s.¹¹ S5.C.9 requires the inclusion of a program to
8 regulate maintenance activities and to conduct maintenance activities by the permittee that
9 prevent or reduce stormwater impacts. S5.C.10 requires that the permittee's SWMP include an
10 education program with the goal of reducing or eliminating behaviors and practices that cause or
11 contribute to adverse stormwater impacts. The performance measures associated with S5.C.2
12 through 10 must be completed within specific time periods. *Testimony of Moore, Wessel, Exs.*
13 *Muni 0001, p. 6-25, Muni 0002, p. 28-42.*

14
15 11.

16 Special Condition S6 (S6), which is similar but not identical to S5, establishes the
17 components required for SWMPs from secondary permittees. Parts of this condition apply to all
18 secondary permittees (S6.A, B and C), all secondary permittees other than the Ports of Seattle
19

20 ¹¹ An illicit connection is any man-made conveyance that is connected to a MS4 without a permit, excluding roof
21 drains and other similar type connections. An illicit discharge is any discharge to a MS4 that is not composed
entirely of stormwater except discharges pursuant to a NPDES permit and discharges resulting from fire fighting
activities. *Ex. Muni 0001, p. 61.*

1 and Tacoma (S6.D), and just the Ports of Seattle and Tacoma (S6.E). *Testimony of Moore, Exs.*

2 ~~*Muni-0001, p. 25-39, Muni-0002, p. 42-47.*~~

3 12.

4 Special Condition S8 (S8) addresses monitoring. It requires the primary permittees and
5 the Ports to develop and implement long-term monitoring programs for the purpose of meeting
6 two of the four monitoring objectives identified in the first round of the Phase I municipal
7 stormwater permits issued in 1995: (1) estimating pollutant concentrations and loads from
8 representative areas or basins; and (2) evaluating the effectiveness of selected Best Management
9 Practices (BMP). The permit does not require monitoring to identify specific sources of
10 pollutants or the degree to which stormwater discharges are impacting selected receiving waters
11 and sediments. *Testimony of Moore, O'Brien, Exs. Muni 0001 p. 40-49; Muni 0002, p. 49-50.*

12 C. Monitoring provisions in S8

13 13.

14 Special Condition S8.C.1 specifies that the primary permittees' and the Ports' monitoring
15 programs must contain three components: 1) stormwater outfall monitoring, which is intended to
16 characterize stormwater runoff quantity and quality at a limited number of locations 2) Targeted
17 stormwater management program effectiveness monitoring, which is intended to improve
18 stormwater management efforts by evaluating at least two stormwater management practices that
19 significantly affect the success of, or confidence in, stormwater controls, and 3) BMP evaluation
20 monitoring, which is intended to evaluate the effectiveness and operation and maintenance
21 requirements of stormwater treatment and hydrologic management BMPs. S8.D, E, and F set out

1 the requirements for each of the three components. *Testimony of Moore, O'Brien, Exs. Muni*
2 ~~0001, p. 40-49; Muni-0002, p. 49-56.~~ A Quality Assurance Project Plan (QAPP) must be
3 prepared for each of the components of the monitoring program in accordance with Ecology
4 guidelines and submitted to Ecology for review. Ecology must review and approve the QAPPs
5 for stormwater monitoring conducted under S8.D and F prior to monitoring. *Ex. Muni 0001, p.*
6 *40-41.*

7 14.

8 The first component of the Special Condition S8 monitoring involves outfall monitoring
9 for the purpose of developing local knowledge of pollutant loads and average event mean
10 concentrations from representative areas drained by MS4s. Developing a baseline of local data
11 is important because some variations are emerging between stormwater characterization data
12 from the Pacific Northwest and other areas around the county and world, with examples of both
13 higher and lower concentration levels present regionally, differing from national averages. To
14 accomplish this objective, the Permit requires permittees to select three sites that represent
15 different land uses and then to monitor a certain percentage of storm events per year for a wide
16 range of constituents and parameters. The permit requires storm events to be sampled using
17 flow-weighted composite storm sampling. S8.D.2.b. The seasonal first-flush must be tested for
18 toxicity. S8.D.2.d. Grab samples from each storm must be taken and tested for total petroleum
19 hydrocarbon and fecal coliform bacteria, and one to three sediment samples must be collected
20 each year at each site and analyzed for a variety of parameters. S8.D.2.e, f. *Testimony of*
21 *O'Brien, Moore, Ex. Muni 0001, p. 41-45.*

9
10
11
12
13
14
15
16
17
18
19
20
21

15.

~~The number of samples is intended to establish a sufficient database from which to~~
discern annual and seasonal loading trends over a long time period. Performing a toxicity test on
the "seasonal first-flush storm" provides an annual worst case scenario. Ecology believes this
data is necessary to evaluate whether stormwater management programs are making progress
towards the goal of reducing pollutants discharged and protecting water quality. The data would
also be useful when establishing Water Clean-up Plans (TMDLs) for water bodies not currently
achieving water quality standards, and in other efforts to identify sources of toxicant loading to
Puget Sound. *Testimony of O'Brien, Ex. Muni 0002, p. 49-53.*

16.

The second component of the S8 required monitoring, described in detail in S8.E, is the
targeted stormwater management program effectiveness monitoring. In this section, each
permittee must conduct monitoring designed to determine the effectiveness of (1) a targeted
action (or narrow suite of actions) from their SWMP, and (2) achieving a targeted environmental
outcome. The monitoring must, at a minimum, include stormwater, sediment or receiving water
monitoring of physical, chemical and/or biological characteristics, and may also include other
kinds of data collection and analysis. Ecology anticipates that the targeted environmental
outcomes permittees will chose to evaluate will be measured in the receiving water and,
therefore, may involve receiving water monitoring. *Testimony of O'Brien, Moore, Exs. Muni
0001, p. 45-46; Muni 0002, p. 53-54.*

1

17.

2

The third component of the S8 monitoring provisions is BMP effectiveness monitoring,

3

the requirements of which are set out in S8.F. The purpose of this third component of the S8

4

monitoring is to develop local performance data on the effectiveness of specific treatment BMPs

5

in reducing pollutant discharges and the effectiveness of various low impact development (LID)

6

practices in reducing the quantity of runoff. This section requires the primary permittees and

7

Ports to select and monitor two treatment BMPs in use at a minimum of two sites in their

8

jurisdiction. S8.F.2. The permittees are also required to monitor the effectiveness of one flow

9

reduction strategy¹² that is in use or planned for installation in their jurisdiction. S8.F.7. Though

10

many of these treatment BMPs have been in common use for many years, and the 2005

11

Stormwater Management Manual for Western Washington relies on them as presumptively

12

effective, Ecology has only incomplete information about their actual pollutant removal

13

capabilities. *Testimony of O'Brien, Exs. Muni 0001, p. 46-47; Muni 0002, p. 54-56.*

14

18.

15

In the absence of local data, Ecology had relied on an existing national stormwater

16

treatment BMP database,¹³ as its primary source of BMPs for the 2005 Stormwater Management

17

Manual for Western Washington (The Manual) *Testimony of O'Brien, Tobiason, Exs. PI 0059,*

18

0060, 0064 and 0065. The national database is of limited utility, however, in evaluating the

19

20

¹² A flow reduction strategy is an approach that reduces the volume of runoff coming off a landscape. Ecology witness Ed O'Brien indicated in his testimony that this referred to the use of low impact development techniques.

21

¹³ The purpose of the database, called the International Stormwater Treatment Database, is to facilitate understanding about how particular BMPs perform database and contains studies from both inside and outside the United States. *Testimony of O'Brien.*

1 effectiveness of BMPs because the performance of treatment BMPs varies greatly depending on
2 ~~specific design criteria, loading criteria, different rainfall patterns, and the types and sizes of~~
3 solids to which a site gets exposed. These factors vary widely across the country, and therefore
4 BMP performance data from one area is not always useful for another area. This has been a
5 specific concern for Washington because, until recently, there has been little Washington data in
6 the database. In some instances, this national database lacks also data quality, and relies on an
7 insufficient number of samples at a particular site or from a particular BMP to be statistically
8 useful. So, while there exists national data that allows Ecology to make some general
9 assumptions about how well BMPs perform, Ecology still lacks site-specific, region-specific data
10 to verify that the BMPs perform the way Ecology anticipates they will perform. As a result,
11 Ecology required permittees to evaluate BMP effectiveness in an effort to learn and apply the
12 information in future settings and permit iterations. *Testimony of O'Brien, Tobiasson, Kibbey,*
13 *Exs. PI 0059, 0060, 0064, 0065, Muni 0002, p. 54-56.*

14 19.

15 Ecology considered requiring receiving water monitoring in the Phase I Permit, but the
16 municipalities as a group opposed the requirement. The 1995 Phase I Permit identified one
17 monitoring objective as evaluating the degree to which stormwater discharges impact selected
18 receiving waters and sediments, and Ecology concedes this continues to be a valid long-term
19 objective for the municipal stormwater general permits. In the current iteration of the Phase I
20 Permit Ecology decided, however, that receiving water monitoring data would not be the most
21 helpful monitoring data because 1) receiving water monitoring data is more complex data to

1 obtain, 2) samples can be hard to collect during storms, and 3) it is difficult to tie the receiving
2 ~~water data back to a specific discharger. Ecology agreed with the municipalities that certain~~
3 receiving waters may receive pollution from multiple upland sources, and monitoring the
4 receiving water would not provide permittees with useful data by which they could develop or
5 tailor their stormwater management programs. Ecology also does not typically require receiving
6 water monitoring under several other general stormwater discharge permits, including the
7 construction and industrial permits, except for certain impaired water bodies where there have
8 been violations of discharge limitations. *Testimony of Moore, O'Brien, Ex. Muni 0002, p. 49.*

9 20.

10 The monitoring required by S8 is primarily aimed at developing a uniform baseline of
11 information about the pollutant loading discharging from MS4s, and evaluating the effectiveness
12 of the BMPs that permittees use to control and reduce the pollutants discharging from those
13 systems. Ecology determined this data will be the most useful for establishing what constitutes
14 maximum extent practicable reduction in pollutants from MS4 discharges for future iterations of
15 the municipal stormwater permits. Allowing some municipalities to opt out of these
16 requirements, by substituting different kinds of monitoring, would reduce the robustness of the
17 data set Ecology seeks for establishing this baseline for future permits. *Testimony of Moore,*
18 *O'Brien.*

19 21.

20 Ecology intends to rely on its own monitoring programs, coordinated with and
21 supplemented by other monitoring efforts, to accomplish the receiving water monitoring

1 objectives identified in the 1995 permit. Ecology received an \$800,000 state appropriation to
2 begin work with a collaborative monitoring consortium to identify the elements of a
3 comprehensive receiving water monitoring program, outside of the permit process. Such a
4 monitoring consortium could more fairly distribute the cost of monitoring among all of the
5 entities with an interest in receiving water data and form the basis for effective, region-wide
6 monitoring of receiving water quality in relation to discharge points. Although Ecology is
7 currently organizing the consortium, no water monitoring has been started to date through this
8 program, and inadequate funding currently exists to do so. Outside the consortium, some
9 receiving water monitoring occurs through statewide ambient water quality monitoring and
10 pollutant specific monitoring where a water body is subject to a TMDL. *Testimony of Moore,*
11 *O'Brien, Wessel.*

12 D. Pierce and Clark Counties Monitoring Plans

13 22.

14 Two primary permittees, Pierce and Clark Counties, already have water quality
15 monitoring programs which differ significantly from the monitoring required in the Phase I
16 Permit. The key difference between both of the counties' programs, and the Phase I Permit
17 monitoring requirements, is that the county programs focus on monitoring in the receiving water
18 environment. However, neither of the County programs monitors the chemical composition or
19 toxicity of stormwater discharges from their MS4, nor relates stormwater management actions to
20 a reduction in the pollutant characteristics of stormwater. *Testimony of Tobiasson, O'Brien, Exs.*
21 *PSA 018, PI 0042.*

1 23.

2 ~~Pierce County began working with a consultant in 2004 to develop its monitoring~~
3 program. The County developed the program based on the proposed monitoring requirements in
4 an early draft of the Phase I permit, which included a receiving water monitoring component, as
5 well as ongoing communications with Ecology personnel. The 2005 draft of the Phase I permit
6 prescribed two of the five monitoring methods that Pierce County incorporated into its
7 monitoring plan. *Ex. PI 0041*. Pierce County published its final program in March, 2007.
8 *Testimony of Tobiason, O'Brien, Ex. PI 0042.*

9 24.

10 The overall goal of the Pierce County monitoring program is to implement a
11 comprehensive monitoring program that will provide meaningful data to support the County's
12 efforts to protect receiving waters from stormwater impacts. Although developed primarily in
13 anticipation of the NPDES permit requirements, it also serves other county water quality
14 objectives. In order to accomplish its goal, the program uses a three level receiving water
15 monitoring approach. It includes long term status and trends monitoring, which includes a triad
16 of bioassessments, physical channel characterization, and in-situ bioassays at existing County
17 monitoring sites in selected streams, and may also include flow monitoring where gauges exist.
18 Pierce County includes the sampling of the stream bottom as part of this long-term monitoring in
19 order to determine the presence and health of benthic invertebrates. Monitoring benthic
20 invertebrates provides a good indicator of watershed health because these organisms respond to
21 physical and chemical stresses at the stream bottom. Pierce County applies these monitoring

1 methods over a five year period to characterize the receiving waters in up to nine watersheds
2 with regards to the receiving waters' physical stability, habitat, biological health, and
3 susceptibility to toxicants in stormwater. This will enable Pierce County to prioritize responses
4 to watersheds that exhibit vulnerability. It also includes targeted development monitoring, which
5 compares upstream and downstream conditions to assess impacts of stormwater discharges on
6 the receiving waters over finite periods before and after specific development. Targeted
7 development monitoring includes continuous turbidity, conductivity and hydraulic stage
8 monitoring and *in-situ* bioassay upstream and downstream of discharges from targeted
9 development, and assessment of physical channel conditions downstream. Some aspects of the
10 County's monitoring program, particularly the real-time data, will also assist the county in
11 detecting spills and illicit discharges. The third level of receiving water monitoring included is a
12 special studies monitoring. This method provides for adaptive management to be employed as
13 needed on a site specific basis to develop cause-effect relationships that lead to focused
14 stormwater management response. As part of this method, chemical analysis may be conducted
15 if other programs indicate a need for such study to determine the cause of a problem discovered
16 through receiving water monitoring. This is the only aspect of the Pierce County Program that
17 provides for the use of chemical analysis. *Testimony of Tobiason, Kibbey, Exs. PI 0042, Ex. PI*
18 *0055, PI 0094.*

19 25.

20 Clark County, like Pierce County, has its own monitoring plan which is focused on
21 receiving water monitoring. Clark County developed its plan in response to its first

1 NPDES/State Waste permit which was issued July, 1999 and expired December, 2000.¹⁴ *Muni*
2 *0140, Special Condition S5.B.4, p. 7, 8.* Its plan has three elements: a long-term index site
3 project, hydrologic monitoring, and a stormwater needs assessment program. The index site
4 project involves nine stream stations which are influenced by stormwater, and a forested
5 reference site. A suite of stream health characteristics are monitored at each site. Water quality
6 monitoring takes place on a monthly basis. The hydrologic monitoring consists of monitoring
7 stream flow continuously through the use of storm gauges at several locations, including some of
8 the site index locations. The stormwater needs assessment program is a system created to make
9 an assessment of needs for each sub-basin in the county that contains parts of the MS4.
10 Currently, Clark County is in the process of completing reports on 12 urbanizing and rural sub-
11 watersheds. *Testimony of Swanson, Ex. Muni 0140, p. 7-8.*

12

26.

13

14

15

16

17

18

19

20

21

¹⁴ Clark County was not informed of the need to submit a permit application until January of 1995, because of confusion over whether Clark County met the requirements of the Phase I Permit, i.e. urbanized area with a population greater than 100,000. *Ex. Muni 0141, p. 8.*

1

27.

2

~~Ecology stated that it was extremely important to be able to answer whether our~~

3

stormwater programs are adequate to protect aquatic resources and uses in its 2004 report to the

4

Legislature. Therefore, Ecology included recommendations that certain types of environmental

5

monitoring be conducted at the local and regional levels, including monitoring of the biological,

6

chemical, and physical health of receiving waters. *Ex. ECY 6 (Phase I), p. 31-32.*

7

28.

8

Ecology does not oppose the Counties continuing on with their own monitoring programs

9

in addition to the S8 monitoring. However, it has not allowed Pierce and Clark Counties to

10

substitute their programs for the required S8 monitoring. Ecology witness Edward O'Brien did

11

not rule out the possibility that Ecology could allow Pierce and Clark to substitute their

12

monitoring programs for some parts of the required S8 monitoring. Pierce County witness

13

Heather Kibbey testified that Pierce County could not afford to do both its receiving monitoring

14

program and the required S8 monitoring. *Testimony of O'Brien, Tobiason, Kibbey.*

15

E. Ports

16

29.

17

One of the required elements of the SWMP for all Phase I permittees is the preparation of

18

a stormwater pollution prevention plan (SWPPP). The permit requires all primary permittees to

19

prepare SWPPS for "all heavy equipment maintenance or storage yards, and material storage

20

facilities owned or operated by the Permittee(s)" that are not already covered by another

21

stormwater discharge permit. S5.C.9.b.xi, p. 23, 24. The primary permittees are allowed 24

1 months to complete the development of their SWPPPs. The secondary permittees, other than the
2 Ports, are required to prepare SWPPPs for "material storage areas, heavy equipment storage
3 areas, and maintenance areas" not covered by another stormwater discharge permit. S6.D.6.a.vi,
4 p. 32. Their SWPPPs must also be completed within three years from the date of permit
5 coverage. *Testimony of Moore, Ex. Muni 0001, p. 23, 24, 32.* In contrast, the Ports' SWPPP
6 preparation requirement, found in S6.E.7, requires the Ports to prepare SWPPPs "all Port-owned
7 lands" that are not covered by another stormwater discharge permit. The Ports are allowed 24
8 months to develop and implement their SWPPPs. *Ex. Muni 0001, p. 38.*

9 30.

10 The Port of Seattle estimates this requirement will involve the preparation of SWPPPs for
11 approximately 44 properties covering approximately 27 percent of its total Seaport acreage (286
12 acres).¹⁵ Some of these sites include port-controlled and operated facilities with multiple tenants,
13 such as Shilshole Marina and Fisherman's Terminal, and several others consist of tenant-
14 controlled container areas. *Testimony of Guthrie, Exs. PI 0020, 0022.* The Port of Tacoma has
15 identified several port-owned sites that are not covered by other stormwater discharge permits,
16 some of which include buildings and parking lots leased to other businesses, others of which
17 consist of environmental mitigation sites. *Testimony of Graves, Ex. PI 0039.*

18 31.

19 The Phase I fact sheet explains Ecology's general thinking regarding SWPPP preparation
20

21 ¹⁵ By agreement with Ecology, SWPPPs will not be required on "no discharge" properties, which include Port-owned parks and properties with connections to Metro Stormwater Conveyances.

1 for the primary permittees. It states:

2 Ecology has determined that activities at certain sites owned or operated by permittees
3 are potentially similar to activities at sites regulated under the Industrial Stormwater
4 General Permit. For this reason this provision of the permit calls for developing
5 Stormwater Pollution Prevention Plans (SWPPPs) for these sites.

6 *Ex. Muni 0002, p. 41.*

7 32.

8 In the 2005 draft of the Phase I Permit, Ecology required SWPPP preparation for "all
9 Port-owned lands with potential pollutant-generating sources." *Ex. PSA 018, p. 37.* The final
10 permit eliminated the qualifier because Ecology expected that all port-owned lands would be
11 pollutant-generating sources, although Ecology did not consider wetland mitigation areas owned
12 by the Port of Tacoma when it made this decision. *Testimony of Graves, Moore, Exs. PSA 018,*
13 *p. 37; PI 0022, 0025-0027.*

14 33.

15 The Port of Tacoma owns several environmental mitigation sites (i.e. wetlands). Most of
16 these sites probably discharge directly to surface or ground waters of the state, and not to the
17 MS4. For the ones that do discharge to the MS4, there is only a small potential that the
18 discharges would carry pollutants. Therefore, preparation of SWPPPs on these sites is unlikely
19 to result in any corresponding water-quality benefits. *Testimony of Moore, Graves.*

20 34.

21 Ecology also explains in the fact sheet its reasons for providing a slightly different

1 standard for the Ports regarding SWPPP preparation. It states:

2 Ecology has determined that special consideration is needed for the Ports of Seattle and
3 Tacoma, distinguishing them from the broader group of Secondary permittees such as
4 diking and drainage districts and public universities. These ports are both located on
5 urban bays with documented water quality and sediment contamination problems that
6 may be linked to stormwater discharges. The infrastructure in both Seattle and Tacoma is
7 fairly old and the MS4s are heavily interconnected between each port and the respective
8 city. Also, both ports lease properties to tenants, of whom many, but not all, are required
9 to have coverage under the Industrial Stormwater General Permit. For these reasons this
10 permit establishes SWMP components that are specific to these two entities.

11 *Ex. Muni 0002, p. 43.*

12 35.

13 In general, the permit has more requirements for primary permittees SWMPs than it does
14 for the Ports. Contrast S5.C. 1 through 10 (establishing 10 components for primary permittees
15 SWMPs) p. 6-25 with S6.E (establishing 7 components for Ports SWMPs) p. 32-39. The source
16 control program for existing development, which is a component of both primary permittees and
17 the Ports SWMPs, also imposes more requirements on the primary permittees than it does the
18 Ports. Contrast S5.C.7, p. 13-15, with S6.E.7, p. 38-39. Further, the scope of the primary
19 permittees source control obligation is much wider than that of the Ports, because the primary
20 permittees are dealing with thousands of different sources, compared to a much more limited
21 number for the Ports. Therefore, the Ports will be preparing a much smaller number of SWPPPs
than the primary permittees. While Ecology suggests that the Guidance Manual for Preparation
of SWPPPs for Industrial Facilities can be used to assist in preparation of Port SWPPPs, it also
encourages the use of generic SWPPP provisions for sites grouped by type of activity, such as

1 parking lots. *Testimony of Moore, Guthrie, Exs. Muni 0001, p. 6-25, 33-39, Muni 0002, p. 44, PI*

2 0021.

3 36.

4 The Port of Seattle expects its tenant businesses to be involved in the preparation of the
5 required SWPPPs because they have the most familiarity with the pollution-generating activities
6 and source control opportunities at the individual sites, but the port, in its role as property
7 manager, will work cooperatively with tenants through its routine compliance assessment
8 process. For example, it has already provided its tenants with templates for preparing the
9 SWPPPs. This process will involve some cost and effort on the part of the tenants, but can also
10 serve as an opportunity for educating and training tenants in issues related to stormwater
11 management. *Testimony of Guthrie.* The Port of Tacoma intends to prepare the SWPPPs for its
12 existing tenant facilities which will require the port to become better informed about the details
13 of its tenant operations and pollutant-generating activities. For new facilities, the Port of Tacoma
14 intends to direct tenants to prepare the SWPPPs. *Testimony of Graves.*

15 F. Low Impact Development (LID)

16 37.

17 The major contention of PSAs' challenge to the Phase I permit is that traditional
18 structural engineered stormwater management practices are inadequate to address the municipal
19 stormwater problem and that the Permit should have also required greater use of Low Impact
20 Development (LID) practices on a broader and more comprehensive scale.

20

21

In the Phase I Permit, Ecology chose to regulate stormwater discharges from new development and redevelopment primarily through the imposition of a flow control standard. S5.C.5.b.i. *Ex. Muri 0001, p. 9, Testimony of O'Brien*. The flow control standard generally requires new and redeveloped sites that discharge to surface waters to control the rate at which stormwater is released from their sites so that the discharges do not cause accelerated stream channel erosion. The flow control standard is not a LID concept, because, in contrast to LID techniques, it is based on the premise that there will be discharges of stormwater from particular sites, and it attempts to control the duration and frequency of high stormwater runoff flows. Conventional stormwater management criteria frequently incorporate a post development peak discharge rate for a 2- and 10-year storm event based upon possible property damage due to flooding and stream bank erosion. These are becoming more recognized as insufficient because they do not address the loss of storage volume to provide for groundwater recharge, they do not adequately protect downstream channels from accelerated erosion, and the inspection and maintenance costs are an increasing burden for local governments. The goal of LID, on the other hand, is to minimize or prevent entirely the discharge of stormwater from the site. While utilization of LID techniques may be useful (or even in some cases necessary) to meet the flow control standard on a particular site, the flow control standard does not require the use of LID techniques. *Testimony of O'Brien, Booth, Exs. ECY 4 (Phase I) p. 2-30 through 2-35, Ex. PSA-053, p. 7.*

1 39.

2 In order to meet the Permit's flow control standard(s), facilities must be engineered so
3 that discharges are not predicted to exceed the predevelopment flow "durations" for a range of
4 storm events. The Stormwater Management Manual gives detailed design specifications for
5 sizing and constructing detention/retention facilities to meet the flow control standard. The
6 Manual itself recognizes the shortcomings of the use of engineered stormwater conveyance,
7 treatment and detention systems to control stormwater. It states, at page 1-25:

8 [These techniques] can reduce the impacts of development to water quality and
9 hydrology. But they cannot replicate the natural hydrologic functions of the natural
10 watershed that existed before development, nor can they remove sufficient pollutants to
11 replicate the water quality of pre-development conditions.

12 The primary focus of detention standards is on mitigating the worst impacts of large storm
13 events. These standards have little or no effect on small storm events, which can also cause
14 damaging increase in flows. Stated another way, the flow control standard addresses large
15 stormwater flow rates only, which occur only a small percentage of time (1%), and provides only
16 residual control to runoff the remainder of the time. *Testimony of O'Brien, Booth, Ex. ECY 4*
17 *(Phase I), p. 1-25, 2-30 through 2-35.*

18 40.

19 Another limitation of the flow control standard comes from a significant exception to the
20 requirement to achieve pre-developed discharge rates for basins that have had at least 40 percent
21 total impervious area since 1985. Phase I permit, Appendix 1, p. 25-27, and Manual, Section
2.5.7 Minimum Requirement # 7, pp. 2-33. For sites in these basins, the pre-developed condition

1 to be matched is the existing land cover. Most areas located within the Seattle city limits, many
2 areas within the City of Tacoma, and some areas in Bellevue and Everett would qualify for this
3 exception. *Testimony of O'Brien, Booth, Exs. ECY 4 (Phase I), p. 2-33, Muni 0001, Appendix 1,*
4 *p. 25-27.*

5 41.

6 The Phase I Permit defines LID as follows:

7 stormwater management and land development strategy applied at the parcel and
8 subdivision scale that emphasizes conservation and use of on-site natural features
9 integrated with engineered, small-scale hydrologic controls to more closely mimic pre-
10 development hydrologic functions.

11 *Ex. Muni 0001, p. 62.* Ecology adopted this definition from the Puget Sound Action Team's
12 Low Impact Development Manual (PSAT Manual), which is a technical manual published in
13 2005 to "provide stormwater managers and site designers with a common understanding of LID
14 goals, objectives, specifications for individual practices, and flow reduction credits that are
15 applicable to the Puget Sound region." *Ex. PSA 050, p.2.*¹⁶ Other definitions of LID offered in
16 testimony at the hearing differ from this definition primarily in the scale of application of LID.
17 Thomas Holz offers an almost identical definition to the one quoted above, but includes
18 application at the watershed scale in addition to the parcel or subdivision scale. *Testimony of*
19 *Holz, Ex. PSA 050, p.11.*

20 _____
21 ¹⁶ The advisory committee for the development of the PSAT Manual included Edward O'Brien, Tom Holz, and
Derek Booth. These three experts also testified at the Phase I hearing, *Testimony of Moore, Ex. PSA 050,*
Acknowledgements page and p. 2.

1 42.

2 While specific definitions of LID may vary, the concept of LID is well-established, and
3 the basic BMPs that constitute LID are well-defined. LID techniques emphasize protection of
4 the natural vegetated state, relying on the natural properties of soil and vegetation to remove
5 pollutants. LID techniques seek to mimic natural hydraulic conditions, reducing pollutants that
6 go into stormwater in the first instance, by reducing the amount of stormwater that reaches
7 surface waters. *Testimony of Horner, Booth, Holz.*

8 43.

9 LID techniques store, infiltrate and evaporate stormwater where it falls rather than collect
10 and convey it to surface waters off site, and can be implemented at an individual development
11 site level, as well as part of a broader strategy employed at a basin or watershed level. Site-level
12 LID BMPs include, but are not limited to, maintenance of natural vegetation on site; reduction of
13 impervious surfaces; protection of natural drainage patterns, use of minimal excavation
14 foundations such as pin foundation for structures; use of vegetated swales to capture and retain
15 runoff; use of green roofs, and storage and reuse of runoff. At a watershed or landscape scale,
16 LID strategies can include basin planning, watershed-wide limits on imperviousness, and
17 protection of sensitive areas like riparian zones, wetland and steep slopes. *Testimony of Holz,*
18 *Booth, Ex. PSA 050.*

19 44.

20 Although many LID techniques are not new ideas (i.e. grass roofs, rain gardens), LID as
21 a formal stormwater management concept was developed in the late 1980's. *Testimony of Booth,*

1 Holz. Prince George's County, Maryland, a pioneer in the area of LID in the United States,
2 began working on bioretention or rain gardens during the 1980's, and published a comprehensive
3 LID technical manual and an accompanying volume providing detailed hydrologic analysis and
4 computational procedures in 1999. Exs. PSA 052 and 053. Two federal agencies, the U.S.
5 Department of Defense and Department of Housing and Urban Development, adopted LID
6 Manuals in 2003 and 2004. Exs. PSA 054 and 055. The Puget Sound Action Team and the
7 Washington State University Pierce County Extension published The PSAT Manual, a 247 page,
8 comprehensive, technical guidance manual for the use of LID in the Puget Sound Area, in
9 January of 2005 with funding provided by the Ecology. Ex. PSA 050. The PSAT Manual was
10 intended to provide a menu of treatment options and direction for site design techniques, but it
11 does not attempt to identify a performance standard for any of the included LID strategies.

12 *Testimony of O'Brien.*

13 45.

14 The Environmental Protection Agency (EPA) has not required the use of LID in its
15 stormwater rules or EPA permits, but it is increasingly supporting and encouraging the use of
16 LID approaches in municipal stormwater programs on its website and thorough numerous
17 publications. See for example, Ex. PSA 057 (EPA National Pollutant Discharge Elimination
18 System (NPDES), Post-Construction Stormwater Management in New Development and
19 Redevelopment) (posted on EPA's website); PSA Ex. 058, (EPA National Pollutant Discharge
20 Elimination System (NPDES), Low Impact Development (LID) and Other Green Design
21 Strategies) (posted on EPA's website); PSA 056 (EPA Fact Sheet for Stormwater Phase II Final

1 *Rule, Post-Construction Runoff Control Minimum Control Measure (Jan. 2000, rev'd 2005); Ex.*

2 *PSA 066 (EPA Low Impact Development (LID), A Literature Review (Oct. 2000); Ex. PSA 059*

3 *(EPA 833-F-04-033, Resource List for Stormwater Management Programs (May 2004); Ex.*

4 *PSA 060 (EPA National Management Measures to Control Nonpoint source Pollution for Urban*

5 *Areas (Excerpts: Cover, Table of Content, Chapters 1-4, 10); Ex. PSA 061 (Memorandum from*

6 *Benjamin Grumbles (Assistant Administrator, EPA) to EPA Regional Administrators Re: Using*

7 *Green Infrastructure to Protect Water Quality in Stormwater, CSO, Nonpoint Source and Other*

8 *Water Programs (Mar. 5, 2007); Testimony of Holz.*

9 46.

10 Ecology's 2005 Stormwater Management Manual addresses the use of LID techniques in
11 several ways, as part of the manual's Minimum Technical Requirements and Site Planning
12 (Volume I), its Hydrologic Analysis and Flow Control Design/BMPs (Volume III), and its
13 Runoff Treatment BMPs (Volume V). *Ex. ECY 4.*¹⁷ One of the most significant changes during
14 the 2005 update to the Manual included the addition of a "credit" system for projects that use
15 LID techniques. *Ex. PSA 064.*

16

17

18 ¹⁷ The Manual is not a regulation but rather a guidance document that presents a presumptive approach to meeting
19 requirements established through other means, such as permits. Washington is somewhat unique in its reliance on
20 the Stormwater Management Manual for directing how stormwater management is to be conducted. *Testimony of*
21 *Moore. Testimony of O'Brien.* The Manual represents Ecology's generalized determination of what constitutes
AKART for stormwater management, without regard to how much horizontal development should be allowed (i.e.,
whether a particular parcel, subdivision, or watershed should be developed or a particular project should be
undertaken). The manual is also considered by the Department of Community, Trade, and Economic Development,
the agency charged with state oversight of the implementation of the GMA, to constitute the best available science
for use by local governments planning under the GMA. *Testimony of O'Brien.*

1 47.

2 Volume I covers several key elements of developing a stormwater site plan, including
3 identifying the minimum requirements for stormwater management at all new development and
4 redevelopment projects. Minimum Requirement #5, which directs on-site stormwater
5 management for the purpose of using inexpensive practices on individual properties to reduce the
6 amount of disruption of the natural hydrological characteristics of the site, requires the use of
7 certain LID BMPs such as roof downspout control and dispersion and soil quality BMPs. This
8 minimum requirement applies to single-family home sites and larger properties. *Testimony of*
9 *O'Brien, Ex. ECY 4 (Phase I), Vol I, at 2-26; Ex. Muni 0001, Appendix I at p.10 and 19.* The
10 Phase I permit requires that permittees' local ordinances must meet Minimum Requirement #5,
11 including requiring specified LID BMPs to reduce the hydrologic disruption of developed sites.
12 *Testimony of O'Brien, Ex. Muni 0001, Condition S5.C.5 (at p. 9) and Appendix 1 (at p.19).*

13 48.

14 Stormwater site planning requirements, also contained in Volume I, direct that site
15 layouts minimize land disturbance and maximize on-site filtration by considering a number of
16 LID strategies and techniques such as preserving areas with natural vegetation (especially
17 forested areas) as much as possible, minimizing impervious areas, and maintaining and utilizing
18 natural drainage patterns. *Testimony of O'Brien, Ex. ECY 4 (Phase I), Vol I, at 3-2.*

19 49.

20 Volume III of the Manual focuses primarily on BMPs to address the volume and timing
21 of stormwater flows from developed sites, for the purpose of providing guidance on the

1 estimation and control of stormwater runoff quantity. Appendix III-C of this volume is
2 Ecology's guidance explaining how Low Impact Development techniques can be represented in
3 approved runoff models so that their benefits in reducing surface runoff can be estimated and
4 credited in the flow duration model. It identifies seven categories of LID techniques, including
5 permeable pavements, vegetated roofs, rainwater harvesting, reverse slope sidewalks, minimal
6 excavation foundations, and rain gardens, and lists the basic design criteria Ecology considers
7 necessary in order to justify use of the suggested runoff credit. *Testimony of O'Brien, Ex. ECY 4*
8 *(Phase I), Vol III, at Appendix III-C.*

9 50.

10 Finally, Volume V of the Manual identifies and discusses BMPs designed to treat runoff
11 to remove sediment and other pollutants at developed sites, for the purpose of providing
12 guidance on the selection, design and maintenance of permanent runoff treatment facilities. LID
13 techniques are included in both the basic and advanced treatment options available to developers,
14 and the method for determining the treatment credits for each technique is explained. Chapter 5
15 of this volume is devoted to the methods for analysis and design of on-site LID BMPs that serve
16 to both control runoff flow rates as well as provide runoff treatment and, since 2005, has directed
17 readers to use the PSAT Manual for various LID BMPs. *Testimony of O'Brien, Ex. ECY 4, Vol*
18 *V.*

19 51.

20 Ecology wrote the first draft of the current Phase I Permit in 1999. At that time, LID was
21 recognized as a stormwater management strategy, but there was not the same body of work

1 available on its use as there is today. Although much of the work and literature cited above post-
2 dated the initial draft of the current Phase I Permit, Ecology recognized that a large body of work
3 existed on LID as it finalized the Phase I permit. Despite the existence of many LID source or
4 reference materials, Ecology believed that it could not at that time define minimum LID
5 requirements, and was unable to define a regulatory performance standard to hold municipalities
6 to, should LID requirements be imposed by the permit. The agency also recognized that local
7 governments had adopted other land use and development standards that were obstacles to the
8 implementation of LID on a broader scale. Some local governments also have limited
9 experience with LID techniques and are reluctant to approve them. *Testimony of O'Brien.*

10 52.

11 Early drafts of the permit included requirements for basin or watershed planning as a LID
12 technique. Use of a basin planning approach in the permit would, among other things, require
13 municipalities to consider the effects of loss of impervious cover to water quality in larger,
14 watershed, basin, and sub-basin areas (potentially measured in many square miles). The ideal
15 area size for basin planning is two to ten acres. WRIA-scale (Water Resources Inventory Area)
16 planning efforts are too large to address the impervious surface problem. *Testimony of Wessel.*
17 Basin planning can also lead to the development of better site specific strategies, and some
18 Ecology staff advocated for its inclusion into the Permit. *Testimony of O'Brien.*

19 53.

20 Ultimately, Ecology drafted a permit that requires municipalities to identify barriers to
21 use of LID, and to take steps to also "allow" LID. Specific requirements for basin planning were

1 not included in the final permit, although the Endangered Species Act listing of various salmon
2 species, and efforts of the Puget Sound Partnership are reasons to reexamine the need for basin
3 planning as a permit requirement. *Testimony of Wessel, Moore; Ex. PSA 31.* Ecology rejected
4 basin or watershed planning as a permit requirement, in part because the agency could not
5 require a comprehensive planning effort, given that not all jurisdictions within a given watershed
6 or basin were covered by the Phase I permit. Ecology also concluded that imposing both site
7 level LID and basin planning requirements would move the agency too far into the land use
8 regulatory arena, although Ecology witnesses conceded that imposition of more detailed LID
9 requirements and a basin planning process could be harmonized with a parallel Growth
10 Management Act land use process, thereby elevating water quality as a growth management
11 planning priority. *Testimony of Moore, Wessel, O'Brien.*

12 54.

13 Ecology stated in its 2004 report to the Legislature that:

14 Compact style development, with a smaller footprint, reduced impervious surfaces,
15 natural areas within the urban core, and improved water detention can help local
16 communities meet the Growth Management Act's goals of accommodating growth while
17 protecting the environment.

18 *Ex. ECY 6 (Phase I), p. 31.* This same 2004 report to the Legislature highlighted the importance
19 of stormwater basin planning in areas which are relatively undeveloped where new development
20 is occurring. Ecology stated that in these areas:

21 site specific controls alone cannot prevent impacts and preserve aquatic resources.
Recent research should be used to identify development strategies that may protect the
resources. Scientific modeling of the basin can help predict the extent of potential

1 impacts and the effectiveness of alternative land development options to help avoid or
2 minimize those impacts.

3 *Id. at 28.* Ecology also recommended in its report to the Legislature that state and local
4 governments consider basin planning to address the known shortcomings of the stormwater
5 permits. Ecology stated that:

6 Stormwater basin planning is needed to quantify flow-related impacts and sources of
7 pollution to urban water bodies. This information is needed to target resources spent on
8 structural and non-structural controls (such as maintenance and public education) so that
9 goals for urban water bodies can be met. In many basins, this planning can be combined
10 with the planning for new development described earlier.

11 *Id. at 30.* Other types of water quality planning are taking place on a WRIA basis. The Board
12 finds that information developed by permittees regarding their use of basin planning, and its
13 possible interface with other planning efforts, would be very valuable to Ecology in its
14 development of the next phase of the Permit.

15 55.

16 The Phase I Permit includes several conditions that address LID in various ways, nearly
17 all of which are in the nature of encouraging or promoting rather than requiring LID by
18 municipalities. In contrast to other permit terms, the final permit does not require municipalities
19 to implement ordinances or other measures to use LID as a primary tool to manage stormwater
20 within their jurisdictions. *See* S5.C.5.b.i (allowing local governments to tailor certain
21 requirements applicable to new development through the use of basin plans or other similar
water quality and quantity planning efforts); S5.C.5.b.iii (requiring SWMPs to allow non-
structural preventative actions and source reduction approaches such as LID techniques);

1 S5.C.6.a (stating that permittees should consider other means to address impacts from existing
2 development “such as reduction or prevention of hydrologic changes through the use of on-site
3 (infiltration and dispersion) stormwater management BMPs and site design techniques, riparian
4 habitat acquisition, or restoration of forest cover and riparian buffers . . .”); S5.C.10.b.(3) and (4)
5 (requiring the inclusion of LID techniques in education and outreach programs); S8.F.1 and 7
6 (requiring monitoring of the effectiveness of one flow reduction strategy that is in use or planned
7 for installation in their jurisdiction); and Appendix 1 § 4.5 (imposing, as a minimum
8 requirement, on-site stormwater management where feasible, including use of roof downspout
9 controls and dispersion and soil quality BMPs or their functional equivalent).¹⁸ *Exs. Muni 0001,*
10 *p. 9, 10, 12, 24, 25, 46, 47, and Appendix 1, p. 19.*

11 56.

12 Some commentors on the draft Phase I Permit criticized the lack of more mandatory LID
13 requirements. The National Marine Fisheries Service and the U.S. Fish and Wildlife Service
14 (jointly the Services) offered comments on the Draft Phase I Permit in May, 2006. While they
15 supported many elements of the draft Permit, the Services recommended that the Permit employ
16 methods to help ensure that several LID projects are completed within the permit term and
17 strongly encouraged the use of basin planning to make better linkage with salmonid recovery
18 plans organized at the watershed level. *Ex. PSA 030.* EPA offered its comments on the draft
19 Phase I Permit in October, 2006. *Ex. PSA 067.* While EPA praised many aspects of the permit,
20 it also recommended strengthening the permit by “promot[ing] the implementation of low impact
21

¹⁸ This same requirement is included in The Manual. *Ex. ECY 0004 (Phase I), Vol. 1, p. 2-26.*

1 development and non-structural best management practices,” and “add[ing] a basin planning
2 program requirement.” Similarly, a group of Washington Scientists sent an “open letter” to
3 Ecology on October 26, 2006, in which they criticized the draft Phase I Permit for its continued
4 focus on “end of pipe” management of stormwater, emphasizing the need to preserve existing
5 “least-disturbed” watersheds, to limit forest loss, and to halt runoff from new impervious areas in
6 the Puget Sound Basin. They recommended broad application of LID principles within the
7 context of land use planning and development regulations efforts to prevent runoff to surface
8 water. *Ex. PSA 010.*

9 57.

10 Ecology staff who developed the Phase I permit, as well as a number of stormwater
11 experts who testified before the Board, agreed that no one stormwater management technique
12 could solve the problem of polluted runoff from municipal stormwater systems. Even the
13 extensive use of site-level LID is not sufficient, on its own, to fully protect aquatic resources.
14 Rather, a combination of aggressive use of LID techniques, best conventional engineering
15 techniques to manage high flows (such as the flow duration standard), and land use actions to
16 preserve a high percentage of native land cover, are necessary to reduce pollutants in stormwater
17 to the maximum extent, and to preserve water quality. Although there is considerable dispute
18 about the attainable performance of particular LID strategies and engineering techniques, there is
19 no dispute that *in combination* these approaches offer the best available, known and tested
20 methods to address stormwater runoff. *Testimony of O'Brien, Holtz, Booth.*

16

17

18

19

20

21

~~There are existing design criteria for many LID techniques, just as there are for~~

traditional BMPs employed to manage stormwater run-off used at the parcel or subdivision scale (for example, pond size or thickness of a liner). These aspects of LID can be employed at a site specific level. However, at this time there are no universal or broadly endorsed performance standards for LID, at either the parcel, subdivision, or watershed scale. Nor were experts before the Board willing to endorse or recommend such standards from among the many potential options identified, although it was undisputed that any permit condition requiring permittees to meet a new stormwater performance standard based on LID would implicate many other local government regulatory schemes, and require modification to local government GMA planning processes and requirements, zoning and development regulations, and building codes. *Testimony of Holz.*

59.

A zero runoff outcome from the use of LID techniques is one such performance standard, but actions to meet that standard would implicate a range of land use planning actions and watershed level assessments. It is possible to create other, more specific performance standards for LID, although the process would involve time and effort. Other jurisdictions are currently using such standards, or have proposed standards for use. For example, jurisdictions can require that LID BMPs be designed in accordance with guidelines in technical manuals, impose specific minimum technical requirements for buildings or roads, require protection of a specific amount of native vegetation at the site or basin level, limit the amount of effective impervious surface,

1 protect the natural hydrograph through various parameters, require maintenance of a certain
2 ~~percentage of predevelopment evapotranspiration capacity or minimize or eliminate surface~~
3 runoff, or require that developers prioritize LID BMPs as the first choice before conventional
4 BMPs. The Phase I Municipal Stormwater Permit for San Diego County, which was reissued in
5 January, 2007, requires all new and redevelopment projects to implement LID BMPs where
6 feasible. The Permittees are given the responsibility of defining the applicability and feasibility
7 of LID BMPs, including the minimum standards to ensure maximum implementation. Another
8 example of an NPDES permit from another jurisdiction that incorporates a LID performance
9 criteria is the Ventura County MS4 Permit. This permit, which was in draft form at the time of
10 the hearing, requires that developers prioritize LID BMPs as the first choice before conventional
11 BMPS. *Testimony of Booth, Holz, Horner, Exs. PSA 048, p. 13-18; PSA 069, p. 49; PSA 070,*
12 *072, 080, Snohomish County Code 30.63C.*

13 60.

14 Requiring municipalities to impose parcel and subdivision-level LID best management
15 practices represents a cost effective, practical advancement in stormwater management. Use of
16 LID techniques at the parcel and subdivision level would not be feasible on every type of site, or
17 under all rainfall conditions present in Western Washington. Use of LID techniques could in
18 some instances allow pollutants to enter groundwater. LID BMPs require maintenance. All of
19 these limitations are also applicable to the more traditional end of pipe BMPs. In fact, site
20 attributes that make implementation of LID techniques difficult also typically make
21 implementation of conventional techniques difficult. In the absence of watershed or basin level

1 efforts to utilize LID, parcel and subdivision-level use of LID will be less effective in overall
2 stormwater management efforts, but still a substantial advancement. *Testimony of O'Brien,*

3 *Booth, Holz, Horner, Exs. ECY 3 (Phase I), p. 34-36, PSA 066, p. 2, 3.*

4 61.

5 In many cases, implementation of LID techniques on the ground for new or
6 redevelopment, or even retrofitting existing development, is less costly, or no more costly, than
7 conventional engineered BMPS. Structural stormwater controls, such as detention ponds, curbs,
8 gutters and pipes, require significant hardware and capital investment. LID techniques eliminate
9 or reduce the need for these structural controls by reducing the volume of water to be managed.

10 LID techniques may also require less space than these traditional methods. *Testimony of Holz,*
11 *Booth, Horner, Exs. PSA 047, p. 6-10, PSA 066, p.1, ECY 3 (Phase I), p. 35-36.*

12 62.

13 A major cost consideration in utilizing LID techniques at a site level is not the
14 engineering or construction associated with the LID techniques, but rather the costs associated
15 with navigating a system of regulation and development that was not created with LID in mind.
16 To fully incorporate LID principles into this system will require review, consideration, and in
17 some instances modification, of existing zoning and building regulations that create obstacles to
18 the use of LID. Some examples of common local government ordinances that could make it
19 difficult to utilize certain LID techniques include requirements related to road width, curbs and
20 gutters, vegetation clearing, and parking spaces. *Testimony of Holz, Horner.* The cost of
21 implementing LID across a broader land use spectrum, through basin or watershed planning is

1 more speculative, and the Board was presented with no clear evidence on costs associated with
2 broader-scale implementation of LID in this manner. Although such planning is underway in
3 certain areas, a longer public and political process could be expected to accompany such an
4 effort.

5 63.

6 The cost of not expanding the application of LID strategies to manage municipal
7 stormwater is very high. The biological health of Puget Sound is declining, and a significant
8 cause of the decline is stormwater run-off. This decline carries with it a variety of
9 environmental, economic, and social costs. *Ex. PSA 087, p. 1.* The Puget Sound Water Quality
10 Plan, which is a plan mandated by the Legislature to be the state's long term strategy for
11 protecting and restoring the Puget Sound, stated as early as 2000 that local governments needed
12 to adopt ordinances that allow and encourage LID practices. *Ex. PSA 078, p. 101.* Many leading
13 scientists concluded, in a paper submitted to the Puget Sound Partnership in July of 2007, that
14 the problem of stormwater must be addressed in the land use context if the health of Puget
15 Sound, the species that inhabit it, and its various important beneficial uses to the region, are to be
16 protected and/or recovered. The group concluded that:

17 We have well documented evidence that the impairment associated with stormwater
18 runoff is primarily a **land use problem**, and that we cannot fully mitigate its effects if we
19 approach it only site-by-site. We know that the problems must be addressed at a basin or
20 landscape level-but we continue to manage land use and stormwater primarily on a site-
21 by-site, end of pipe basis. At the same time, we also know that current site-by-site
development techniques that result typically in wholesale loss of vegetation, compaction
of native soils and connected impervious surfaces, can and should be improved upon
significantly if we are to address stormwater problems.

Ex. PSA -012, p. 3 (emphasis in original).

1

64.

2 Recently, many local governments have begun incorporating LID techniques into their
3 stormwater manuals, and/or adopting LID stormwater requirements. Exs. PSA 072 (City of
4 Olympia, *Engineering Design and Development Standards, Ch. 9, Green Cove Basin*); PSA 073
5 (*Graham Community Plan, A Component of the Pierce County Comprehensive Plan, Excerpts:*
6 *pp. Cover, Table of Contents, p. 70, 87, 109, 149, 208*); PSA 074 (*Gig Harbor Peninsula*
7 *Community Plan, Excerpts: pp. cover, 29, 41, 63, 117, 210*); PSA 076 (*King County,*
8 *Washington, Surface Water Design Manual, Jan. 4, 2005, Excerpts: pp. cover, Table of*
9 *Contents, 5-1 through 5-16*); PSA 051 (*Pierce County, Stormwater Management and Site*
10 *Development Manual, Excerpts: Ch. 10, p. 10-1 to 10-82*).

11

65.

12 Examples of the approaches already being used by Phase I Permittees to encourage or
13 require the use of LID techniques include reducing charges for surface water rates with the use of
14 an approved LID stormwater and surface water runoff systems (*City of Tacoma, Ex. PSA 085, p.*
15 *4*); promoting LID during project scoping meetings with potential developers (*City of Tacoma,*
16 *Ex. PSA 085, p. 4*); adopting LID Ordinances (*Snohomish County, PSA Ex. 077, p. 8*);
17 incorporating LID Development Design concepts into existing regulations (*Snohomish County,*
18 *Ex. PSA 077, p. 9*); and providing public outreach and education about LID (*City of Tacoma, Ex.*
19 *PSA 085, p. 5, Snohomish County, Ex. PSA 077, p. 10-14, City of Seattle, Ex. PSA 079, p. 12, 13*).

20 Other, more stringent examples include requiring project proponents to use LID techniques for
21 all proposed Fully Contained Community developments in rural areas (*Snohomish County, Ex.*

1 *PSA 077, p. 9*); requiring LID for any UGA docket expansions proposals within the Little Bear
2 Creek watershed (*Snohomish County, Ex. PSA 077, p. 10*); and requiring LID to be used on a
3 large project in the Mill Creek pocket expansion (*Snohomish County, Ex. PSA 077, p. 9*).

4 66.

5 The Board finds that LID methods are at this time a known and available method to
6 address stormwater runoff at the site, parcel, and subdivision level. Numerous reference
7 documents, technical manuals, expert testimony, and Ecology's own Stormwater Management
8 Manual, discussed above, support this finding. The Board also finds that LID methods are
9 technologically and economically feasible and capable of application at the site, parcel, and
10 subdivision level at this time. Because application of these methods at the basin and watershed
11 level involves additional cost and practical considerations, we find Ecology must ready for the
12 eventual use of this known and available method of stormwater treatment for future iterations of
13 the permit, consistent with its obligation to impose increasingly stringent requirements on
14 discharges covered by NPDES permits.

15 G. Existing development

16 67.

17 The Phase I Permit addresses stormwater runoff from existing development through the
18 implementation of structural stormwater controls and source controls. Both of these are required
19 components of Permittees' SWMPs, and the Permit includes minimum requirements for each
20
21

1 which are based on EPA's stormwater rules.¹⁹ *Testimony of Wessel, Ex. Muni 0001, p. 12-15,*
2 ~~*Ex. Muni-0002, p. 34-36.*~~

3 68.

4 The structural stormwater control program, also referred to as the "retrofit" component, is
5 targeted at discharges not adequately controlled by other aspects of the SWMP. S5.C.6.
6 Through this program, permittees must consider construction of stormwater control projects, as
7 well as other means to address impacts to state waters caused by MS4 discharges. The permit
8 directs that the program "shall consider the construction of projects such as: regional flow
9 control facilities; water quality treatment facilities; facilities to trap and collect contaminated
10 particulates, retrofitting of existing stormwater facilities; and rights-of-way, or other property
11 acquisition to provide additional water quality and flow control benefits." The Permit also
12 provides that permittees "should consider" other means to address impacts, including LID
13 techniques such as "reduction or prevention of hydrologic changes through the use of on-site
14 (infiltration and dispersion) stormwater management BMPs and site design techniques. . ."

15 S5.C.6.a. *Testimony of Wessel, Ex. Muni 0001, p. 12, 13.*

16 69.

17 The permit establishes minimum performance measures for the structural stormwater
18 control program, including development of the program within 1 year of the effective date of the
19

20 ¹⁹ The Fact Sheet's reference to 40 C.F.R. 122.26(b)(2) appears to be a typographical error. Ecology's pre-hearing
21 brief properly cites the applicable federal regulation for these program elements as 40 C.F.R. 122.26(d)(2). A
portion of this federal rule, unrelated to municipal stormwater, was recently invalidated in *Natural Resources
Defense Council v. U.S. E.P.A.*, 526 F.3d 591 (9th Cir. 2008).

1 permit, and implementation of the program within 18 months from the effective date of the
2 permit. S5.C.6.b.i. Permittees are required to provide a list of planned individual projects that
3 are scheduled for implementation during the term of the permit. Municipalities are not required
4 to prioritize the planned projects in any manner. Permittees are required to submit a description
5 of their structural stormwater control program to Ecology along with the written documentation
6 of their SWMP, but the permit does not set a minimum level of effort for this requirement or
7 provide for Ecology review and/or approval of the structural stormwater control program.
8 S5.C.6.b.ii. *Testimony of Wessel, Dalton, Ex. Muni 0001, p. 12, 13, Ex. Muni 0002, p. 35.*

9 70.

10 The requirements for the Source Control Program for existing development are set out in
11 S5.C.7. Through this program, the permittee must "reduce" pollutants in runoff from areas that
12 discharge to MS4s, through application of operational and structural source control BMPs, and if
13 necessary treatment BMPs to pollution generating sources associated with existing land uses and
14 activities. S5.C.7.a. The program required in this section also must include inspections,
15 application and enforcement of local ordinances at applicable sites, and reduction of pollutants
16 associated with application of pesticides, herbicides and fertilizer discharging to MS4s.
17 S5.C.7.b.ii-iv. While reduction of pollutants is mandated, no objective standard is set for the
18 amount of reduction, although Ecology must review and approve the source control program.
19 S5.C.7.b.i. *Testimony of Wessel, Muni 0001, p. 13-15.* Under this section of the permit,
20 permittees must also implement a progressive enforcement policy to assure compliance with

21

1 stormwater requirements within a reasonable time period. S5.C.7.b.iv. *Testimony of Wessel, Ex.*

2 *Muni-0001, p. 13-15.*

3 H. Timing of Compliance

4 71.

5 PSA challenges the validity of several Phase I Permit provisions on the grounds that they
6 do not require implementation of the permit within three years. PSA provides several examples
7 of permit conditions that allow implementation after three years. Some of these examples
8 include S5.C.2.b.ii (requiring outfalls to be mapped no later than four years from the effective
9 date of the permit); S5.C.8.b.vi (requiring screening for illicit discharges in portion of each
10 jurisdictions to be completed within four years.); and S.5.C.9.b.ii (3) (allowing permittees up to
11 four years after the effective date of the permit to develop a schedule to inspect treatment and
12 flow control facilities). PSA also provides examples of conditions that impose duties that are
13 tied to the expiration of the permit. Some examples of these conditions include Condition
14 S6.A.3 (full development of the co-permittee and secondary permittees' SWMPs no later than
15 180 days prior to the expiration of the permit); and S6.D.1. a.ii (Secondary permittees shall label
16 all inlets 180 days prior to expiration of the permit). *Ex. Muni 0001, p. 7, 18, 20-21, 25, and 27.*

17 72.

18 Any Conclusion of Law deemed to be a Finding of Fact is hereby adopted as such.

19

20

21

1 CONCLUSIONS OF LAW

2 1.

3 The Board has jurisdiction over the parties and the issues in the case pursuant to RCW
4 43.21B.110(1)(c). The burden of proof is on the appealing party(s) as to each of the legal issues,
5 and the Board considers the matter *de novo*, giving deference to Ecology's expertise in
6 administering water quality laws and on technical judgments, especially where they involve
7 complex scientific issues. *Port of Seattle v. Pollution Control Hearings Board*, 151 Wn.2d 568,
8 593-594, 90 P.3d 659 (2004). Pursuant to WAC 371-08-540(2), "In those cases where the board
9 determines that the department issued a permit that is invalid in any respect, the board shall order
10 the department to reissue the permit as directed by the board and consistent with all applicable
11 statutes and guidelines of the state and federal governments."

12 A. Monitoring (Issues C.1, C3, and F.3.)

13 2.

14 Two counties, Pierce and Clark, challenge the monitoring requirements imposed by
15 Special Condition S8.²⁰ They contend that their own monitoring programs, which focus on
16 receiving water monitoring, are more advanced than the monitoring required by S8. While they
17 support Ecology's S8 monitoring approach as a starting point for municipalities that do not
18 already have well developed receiving water monitoring programs, Pierce and Clark Counties
19

20
21 ²⁰ Issues C.1 and C.3.

1 argue that compliance with the S8 monitoring will hinder their own efforts to protect water
2 quality.

3 3.

4 The Utilities also challenge the validity of the S8 monitoring program. They contend that
5 it is deficient because it does not require receiving water or "compliance" monitoring. They
6 argue that receiving water monitoring is necessary to establish whether the permittees have
7 complied with water quality standards and whether they have treated their discharges with
8 AKART or to the maximum extent practicable.²¹

9 4.

10 WAC 173-226-090(1) establishes monitoring requirements for general waste discharge
11 permits. The Board has concluded in its past decisions that this regulation provides Ecology with
12 the discretion to impose *reasonable* monitoring requirements. WAC 173-226-090(1); *Puget*
13 *Soundkeeper Alliance v. Ecology*, PCHB Nos. 05-150, 0151, 06-034, -040 (Jan. 26, 2007) (CL
14 22). Further, since a decision pertaining to monitoring requirements in a general permit falls within
15 an area of Ecology's technical expertise, and involves complex scientific issues, the agency's
16 decision is entitled to deference. *Port of Seattle* at 593-594. The disagreement between appellants
17 and Ecology reflects different sides of a long-standing debate regarding the relative merits of
18 instream versus outfall monitoring, and the most advantageous sequencing of the two. *Ex. PI*
19 *0048*. It is clear there is no one right approach, as the type and timing of monitoring that is best

20
21

²¹ Issue F.3.

1 in any given situation depends on the particular purpose, context, and available resources, among
2 other factors.

3 5.

4 Neither the Utilities nor the Counties have cited to any law requiring the Phase I Permit
5 to require receiving water monitoring. The federal stormwater rules require only that
6 municipalities propose a monitoring program for the term of the permit, but list few specific
7 requirements. 40 C.F.R. 122.26(d)(2)(iii)(D).²² The Board concludes that Ecology's decision
8 not to require receiving water monitoring during this permit cycle is lawful and reasonable.
9 Ecology's decision to require monitoring designed to understand the pollutants discharging from
10 MS4s, and to evaluate the effectiveness of the BMP's in use, will provide the most useful data to
11 establish what constitutes maximum extent practicable reduction in pollutants in discharges from
12 MS4s for future permits. Further, as pointed out by Ecology, the counties are not prohibited
13 from conducting receiving water monitoring in addition to the S8 monitoring required under the
14 permit.²³

15 6.

16 In light of the discretion Ecology has in this area, the deference its technical decisions are
17 entitled to, and the fact that the burden of proof rests on the party challenging the permit, neither
18 the Counties nor the Utilities have presented a sufficient case to convince the Board that it should

19 ²² A portion of this federal rule, unrelated to municipal stormwater, was recently invalidated in *Natural Resources
20 Defense Council v. U.S. E.P.A.*, 526 F.3d 591 (9th Cir. 2008).

21 ²³ It is also possible that parts of the Pierce and Clark County programs could be used to satisfy the targeted
effectiveness component of the S8 monitoring (S8.E). *Ex. Muni 0001*, p. 45-46. The Board encourages Ecology to
work with Pierce and Clark Counties to find ways to make parts of their current monitoring programs satisfy some
of the requirements under S8.

1 reverse Ecology's decision to select the S8 monitoring program and require all permittees to
2 participate in it.

3 B. Ports (Issue E.5)

4 7.

5 The Ports contend that it is "unlawful, unreasonable, unjust, or invalid" to require them to
6 prepare SWPPPs on all port owned land not covered by another discharge permit. The Ports
7 argue that the primary permittees have to prepare SWPPPs only on areas on which industrial
8 type activities occur (maintenance areas and material and heavy equipment storage) that are not
9 covered by another discharge permit. The Ports assert that it is unreasonable to require SWPPPs
10 without consideration to how property is used, it is unreasonably burdensome to the Ports
11 because of the cost to prepare SWPPPs, and it is unnecessary because not all port-owned lands
12 have polluting generating characteristics. The evidence presented, however, does not support
13 these arguments.

14 8.

15 The evidence presented at the hearing establishes that lands owned by the Ports of Seattle
16 and Tacoma are located close to vulnerable urban waters with documented water quality and
17 sediment contamination problems. Almost all of the port-owned lands that discharge to MS4s
18 have pollutant-generating characteristics. Therefore preparation of SWPPPs for these properties
19 will have environmental benefits. The only exception is those few environmental mitigation
20 sites owned by the Port of Tacoma. Most of these environmental mitigation sites probably do
21 not discharge to the MS4s, and therefore would not require coverage under the Phase I Permit.

1 For the ones that do, however, there is no environmental benefit gained by requiring the
2 preparation of a SWPPP, and it is appropriate to exempt these sites from preparation of SWPPPs.

3 9.

4 The Board concludes that it not an unreasonable burden to require the Ports to prepare a
5 SWPPP for all port-owned lands which discharge to the MS4 and are not already covered by
6 another discharge permit. Based on the permit's inventory of types of sites with potential
7 pollutant generating sources (*Muni 0001, Appendix 8*), it was reasonable for Ecology to conclude
8 that the Ports owned most or all of these type of pollution sources, and that the Ports needed to
9 prepare plans to manage stormwater from such port-owned property. The Ports also have fewer
10 requirements under the Phase I Permits than other primary permittees. They will have fewer
11 SWPPPs to prepare than the primary permittees. For SWPPP preparation, they can use some
12 generic conditions for sites with identical uses, such as commercial buildings or parking lots.
13 This will reduce the amount of time it takes to prepare each SWPPP and the cost of preparation.
14 The ports can also work cooperatively with their tenants who share some responsibility for the
15 proper management of stormwater on port-owned properties, which will have the added
16 environmental benefit of educating site operators about stormwater BMPs.

17 10.

18 The Board concludes that Special Condition S6.E.7, which requires the Ports to prepare
19 SWPPPs on all port-owned lands is appropriate and valid. However, the permit should not
20 mandate SWPPP preparation for environmental mitigation sites owned by the Port of Tacoma, as
21

1 the Port of Tacoma has shown that such sites are unlikely to generate untreated stormwater
2 pollution.

3 C: LID (Issue F.1.a & .b)

4 11.

5 The LID issues raised in this appeal involve the question of whether the Phase I Permit fails
6 to meet the required treatment standard of reducing pollutants to the "maximum extent
7 practicable"(MEP) and applying "all known, available and reasonable methods of treatment"
8 (AKART), because the permit does not require more extensive use of LID techniques.

9 12.

10 The Board has previously ruled in this appeal (on summary judgment in the Special
11 Condition S4 proceeding) the CWA requires that NPDES permits issued for discharges from
12 MS4s must reduce pollution to the maximum extent practicable (the "MEP" standard). The
13 Board also concluded the WPCA contains a similar requirement, in that all wastewater discharge
14 permits must incorporate permit conditions requiring all known, available and reasonable
15 methods of treatment to control the discharge of toxicants and protect water quality (the
16 "AKART" standard). Order on Dispositive Motions: S4 issued on April 2, 2008.

17 13.

18 The MEP standard in the CWA provides:

19 Permits for discharges from municipal stormsewers . . . (iii) shall require controls to
20 reduce the discharge of pollutants to the maximum extent practicable, including
21 management practices, control techniques and system, design and engineering methods,
and such other provisions as the Administrator or the State determines appropriate for the
control of such pollutants.

1
2 33 U.S.C. § 1342(p)(3)(B)(iii).

3 Neither Congress nor the EPA have defined the meaning of MEP in the municipal
4 stormwater context, nor do the parties cite to federal court cases interpreting the MEP standard in
5 the municipal stormwater context.²⁴ The Board, in a prior decision pertaining to the first round
6 of the municipal stormwater permits, stated:

7 The MEP standard is unique under water pollution laws and applicable only to municipal
8 stormwater discharges. MEP reflects the difficulty of addressing stormwater on a system
9 wide basis and the focus of regulating municipal stormwater discharges on prevention
and control. This approach by its nature requires extensive planning and *prioritization* to
achieve the underlying goal of meeting water quality standards.

10 *Save Lake Sammamish v. Ecology*, PCHB Nos. 95-78 & 121, Order Granting Summary
11 Judgment (Dec. 12, 1995) (emphasis added).

12 14.

13 The AKART standard originates in state law, but the Legislature has not explicitly
14 defined the term. Ecology has incorporated the state AKART standard into several of its
15 regulatory programs (e.g., the state surface and ground water quality standards, state waste
16 discharge and NPDES permit programs, sediment management standards, and domestic
17 wastewater facilities regulations), and has defined the AKART standard through rulemaking.
18 In the state's surface water quality standards, "AKART" is defined as "the most current
19 methodology that can be reasonably required for preventing, controlling, or abating the
20

21 ²⁴ The term "practicable" as used in a different section of the CWA, 33 USC § 1311(b)(1)(a), has been defined as
meaning that technology is required unless the costs are "wholly disproportionate" to pollution reduction benefits.
Rybacheck v. U.S. EPA, 904 F.2d 1276, 1289 (9th Cir. 1990).

1 pollutants associated with a discharge.” WAC 173-201A-020. The Washington Supreme Court
2 has further clarified that the “reasonableness” prong of AKART involves both technological and
3 economic feasibility. *Puget Soundkeeper Alliance v. Ecology*, 102 Wn. App. 783, 792-793, 9
4 P.3d 892, 897 (2000).

5 15.

6 In evaluating MEP and AKART for the Phase I Permit, we start with the context that this
7 is a “programmatic” permit that regulates the discharge from MS4 systems on a jurisdiction-wide
8 basis, through the municipalities’ implementation of their Stormwater Management Programs.
9 In several instances the permit requires that through these Stormwater Management Programs,
10 municipalities enact ordinances or orders, or adopt other enforceable documents, to control
11 pollution in stormwater. *See, e.g.*, Condition S5.C.1. The nature and scope of the LID
12 provisions in the Permit, and what can be required through the permit, must therefore be
13 evaluated within the broader context of the SWMP requirements and the programmatic nature of
14 this permit.

15 16.

16 The permit’s reliance on a flow control standard as the primary method to control
17 stormwater runoff from MS4s fails to reduce pollutants to the federal MEP standard, and without
18 greater reliance on LID, does not represent AKART under state law. The permit’s reliance on
19 terms that simply require “removal of obstacles” and actions to “allow” use of LID is insufficient
20 to meet these same federal and state pollution control standards. The testimony presented by
21 PSA, the Utilities, and Ecology’s technical experts leads to the indisputable conclusion that

1 application of LID techniques, at the parcel and subdivision level, is a currently known and
2 ~~existing methodology that is reasonable both technologically and economically to control~~
3 discharges entering into MS4s covered by the Phase I Permit. The great weight of testimony
4 before the Board, from various experts and Ecology witnesses, was that in order to reduce
5 pollution in urban stormwater to the maximum extent practicable, and to apply AKART, it is
6 necessary to aggressively employ LID practices *in combination with* conventional stormwater
7 management methods. Thus, we conclude that under state law, the permit must require greater
8 application of LID techniques, where feasible, in combination with the flow control standard, to
9 meet the AKART standard. The permit must also require the application of LID, where feasible,
10 and conventional engineered stormwater management techniques to remove pollutants from
11 stormwater to the maximum extent practicable in order to comply with federal law. Our
12 recognition that use of LID is to be employed where feasible recognizes that, like all stormwater
13 management tools, it too is subject to limitations in its practical application by site or other
14 constraints. See Findings of Fact 49-51. We do not change the applicable legal standard by use
15 of this term. Accordingly, the permit must be remanded for modification in light of this
16 conclusion.

17 17.

18 Although we conclude that the permit must require municipalities to employ broader use
19 of LID at the parcel and subdivision level, we stop short of concluding that the permit must, at
20 this time, require use of LID at a basin and watershed level. Based on the evidence before the
21 Board, we cannot conclude that the current iteration of the permit must require implementation

1 of LID on a basin or watershed scale in order to meet federal and state water quality standards.

2 ~~Little evidence was presented as to the elements and cost of basin or watershed planning that~~

3 would be necessary to implement LID at this level. Ecology testified that the current Phase I and

4 Phase II permits result in a patchwork of regulation of municipal stormwater, and jurisdictions

5 are at greatly varying degrees of readiness to manage stormwater on basin or watershed levels.

6 The Phase II permittees themselves are at greatly varying degrees of readiness and capacity to

7 undertake LID on a basin and watershed level, and would need to work with Phase I and other

8 jurisdictions to do so. Given these several factors, the Board concludes that a permit condition

9 requiring municipalities to implement LID at a basin or watershed level is not, at this time,

10 reasonable or practicable. This is not to say that no steps can or should be taken at this time.

11 Ecology has identified the particular importance of basin planning in areas which are relatively

12 undeveloped where new development is occurring. The Board concludes that city and county

13 permittees should identify such areas where potential basin planning would assist in reducing the

14 harmful impacts of stormwater discharges upon aquatic resources. This will assist Ecology in

15 readying for the next round of permits when such a requirement may be necessary to meet the

16 state AKART standard and, under federal law, to reduce pollutants in municipal stormwater to

17 MEP. As we discuss in further conclusions, we do not find the Growth Management Act to be

18 an impediment to Ecology requiring greater use of LID than represented by the current permit,

19 including at the basin and watershed planning level. Because the CWA and state water quality

20 laws anticipate that there will be increasingly stringent requirements imposed on those that

21 discharge pollutants to the state's waters, including municipalities, efforts to further basin and

1 watershed planning efforts in order to incorporate the known and available LID techniques
2 should begin in anticipation of the next permit cycle.

3 18.

4 No party challenges Ecology's authority to require LID techniques if they are necessary
5 to meet the AKART or MEP standards. The Board affirmed this point in its summary judgment
6 order. Order on Dispositive Motions: (Phase I Municipal Stormwater Permit) (April 8, 2008).

7 The Board further stated:

8 As pointed out by PSA, it is impossible to untangle stormwater management from land
9 use. Even the commonly accepted water quality technique of requiring a stormwater
10 retention pond at a site takes up significant area in a development, potentially reducing
11 the number of buildable sites and constituting a land use restriction. The challenge, as
12 recognized by both Ecology and PSA, is to most effectively harmonize Ecology's
13 authority over site design and land use standards under the water pollution laws with
14 other state laws that are specifically aimed at addressing land use on a broader scale.

15 *Id.* While Ecology does not dispute that it has the authority to require the use of LID techniques,
16 it was constrained in the full exercise of this authority because of concerns about intruding too
17 far into local government land use planning efforts under the Growth Management Act.

18 Ecology's position is somewhat puzzling, as it has, through various requirements of its
19 Stormwater Management Manual, and the permit itself, already required a number of LID
20 techniques, and has required local government to remove obstacles to use of the same.²⁵ The

21 ²⁵ We also note that, in another context, Ecology has recently adopted rules for the implementation of the Shoreline
Management Act which outline a comprehensive process for preparing or amending shoreline master programs that
requires, among other things, local governments to incorporate the most current, accurate, and complete scientific
and technical information available that is applicable to the issues of concern; prepare a characterization of shoreline
ecological functions, including hydrologic functions; identify water quality and quantity issues relevant to master

1 Board concludes that contrary to the concerns raised by Ecology during permit development, that
2 the GMA is not a barrier to greater use of LID but rather complements the efforts of Ecology to
3 move forward with requiring the use of LID techniques under the Phase I Permit.

4 19.

5 The Legislature enacted the Growth Management Act (GMA), Ch. 36.70A RCW in 1990
6 and 1991, largely "in response to public concerns about rapid population growth and increasing
7 development pressures in the state, especially in the Puget Sound region." *Quadrant Corp. v.*
8 *State Growth Management Hearings Bd.*, 154 Wn.2d 224, 231-232, 110 P.3d 1132, 1136 (2005)
9 (citations deleted). The GMA includes a broad statement of goals to guide local governments in
10 their development and adoption of comprehensive plans including a goal to "Protect the
11 environment and enhance the state's high quality of life, including air and water quality. . ."
12 RCW 36.70A.020(10).

13 20.

14 The GMA mandates that local governments adopt comprehensive plans which include,
15 among other elements; a land use element addressing, "drainage, flooding, and stormwater run-
16 off in the area and nearby jurisdictions" and providing "guidance for corrective action to mitigate
17 or cleanse those discharges that pollute waters of the state, including Puget Sound or waters
18 entering Puget Sound." RCW 36.70A.070(1); *Swinomish Indian Tribal Community v. Skagit*

19
20
21 program provisions; identify important ecological functions that have been degraded through loss of vegetation; and
identify measures to ensure that new development meets vegetation conservation objectives. WAC 173-26-201.

1 Co., 138 Wn. App. 771, 774, 158 P.3d 1179 (2007) (concluding that the GMA mandates that
2 local governments adopt comprehensive plans to protect surface and ground water resources.)

3 21.

4 The state WPCA predated the GMA, with the specific purpose of protecting the waters of
5 the state. RCW 90.48.010. The Legislature tasked Ecology with the job of implementing the
6 WPCA. RCW 90.48.030, .035. Clearly, there is an area of interface and overlap between the
7 GMA and the WPCA.

8 22.

9 The Washington Courts have stated that statutes are to be read together harmoniously
10 whenever possible. "The construction of two statutes shall be made with the assumption that the
11 Legislature does not intend to create an inconsistency." *Peninsula Neighborhood Ass'n v. Dep't*
12 *of Transportation*, 142 Wn.2d 328, 342, 12 P.3d 134 (2000). Further, as the Washington
13 Supreme Court recently stated: "We do not favor repeal by implication, and where potentially
14 conflicting acts can be harmonized, we construe each to maintain the integrity of the other".
15 *Anderson v. State, Dept. of Corrections*, 159 Wash.2d 849, 859, 154 P.3d 220, 225 (2007) (citing
16 *Misterek v. Washington Mineral Products, Inc.*, 85 Wn.2d 166, 168, 531 P.2d 805 (1975)). See
17 also *Kariah Enterprises, LLC v. Ecology*, PCHB No. 05-021, Corrected Order Granting Partial
18 Summary Judgment (Jan. 6, 2005).

19 23.

20 The Board has addressed the interface between the GMA and the WPCA in the *Kariah*
21 decision, cited above. In that case, the appellant challenged Ecology's denial of a CWA Section

1 401 Water Quality Certification for a proposed residential development. The Appellant argued
2 that the Legislature, through GMA, had delegated Ecology's authority over wetlands under the
3 WPCA to local governments. The Board rejected this argument, concluding that neither chapter
4 90.48 RCW nor 36.70A RCW contained any express provisions delegating Ecology's authority
5 over protecting water quality in wetlands to cities and counties. The Board went on to conclude
6 that the WPCA and the GMA should be harmonized, and that:

7 The legislative policy articulated in RCW 36.70A.010 indicates the GMA was directed at
8 addressing uncoordinated and unplanned growth, not at shifting the responsibility to
9 regulate wetlands from the state government to local governments.

9 *Kariah*, CL 33.

10 24.

11 Similarly, in a Shoreline Hearings Board decision addressing the interaction between the
12 Shoreline Management Act (SMA) and the GMA, the Board concluded that Ecology's newly
13 adopted shoreline rules did not improperly usurp the authority of local governments planning
14 under the GMA, despite venturing into land use controls. *Association of Washington Businesses*
15 *v. Ecology*, SHB No. 00-037, Order granting and denying appeal (2001)(Issue 9).²⁶

16
17
18 ²⁶ Although this decision was split on several issues, the holding on the GMA issue was unanimous. We note that
19 even prior to the GMA, the Shoreline Management Act (SMA), Ch. 90.58 RCW, was enacted by initiative of the
20 people in 1971 after recognizing the "ever increasing pressures of additional uses ... being placed on the shorelines
21 necessitate[e] increased coordination in the management and development of the shorelines of the state." RCW
90.58.020. The SMA includes a broad policy to protect the waters of the state and gives preference to uses that
protect water quality and the natural environment. *Id.* The SMA establishes a balance of authority between local
and state government, where cities and counties have the primary responsibility for initiating the planning required
by the Act and administering the regulatory program, and Ecology is tasked with providing assistance to local
governments in the development of their shoreline master programs and "insuring compliance with the policy and
provisions of [the Act]." RCW 90.58.050.

25.

1

2

The Legislature has not expressed any intent, either through the GMA, SMA, or

3

amendments to the WPCA, to redirect Ecology's role in water quality protection to the local

4

governments. The Department of Community, Trade and Economic Development (CTED), the

5

agency charged with implementing and interpreting the GMA, has considered the interaction

6

between the GMA and pre-existing laws not specifically addressed in the GMA. In WAC 365-

7

195-700, CTED's GMA regulations state:

8

For local jurisdictions subject to its terms, the Growth Management Act mandates the development of comprehensive plans and development regulations that meet statutory goals and requirements. These plans and regulations will take their place among existing laws relating to resource management, environmental protection, regulation of land use, utilities and public facilities. Many of these existing laws were neither repealed nor amended by the act.

9

10

11

This circumstance places responsibilities both on local growth management planners and on administrators of preexisting programs to work toward producing a single harmonious body of law.

12

13

WAC 365-195-700 (emphasis added).²⁷

14

15

CTED's regulations further explain that:

16

Overall, the broad sweep of policy contained in the act implies a requirement that all programs at the state level accommodate the outcomes of the growth management process wherever possible. State agencies are rarely concerned solely with the rote application of fixed standards. The exercise of statutory powers, whether in permit functions, grant funding, property acquisition or otherwise, routinely involves such agencies in discretionary decision-making. The discretion they exercise should now take into account the new reality of legislatively mandated local growth management

17

18

19

20

²⁷ Ecology's SMA rules recognize a similar responsibility to harmonize overlapping bodies of law and regulation, which now provide: "It is the responsibility of the local government to assure consistency between the master program and other elements of the comprehensive plan and development regulations." WAC 173-26-191(e).

21

1 programs.

2 WAC 365-195-765(4).

3

26.

4

5 The Phase I permittees are all cities and counties required to plan under the GMA. RCW

6

7 36.70A.040. Their planning must address protection of surface and ground water. RCW

8

9 36.70A.070(1). CTED has identified the Ecology Stormwater Management Manual as best

10

11 available science in regard to stormwater management under the GMA. Ecology, as a state

12

13 agency, must also work toward implementation of the GMA. We conclude that there is no

14

15 conflict between GMA and the WPCA, nor the roles of local governments and Ecology under

16

17 these statutes. These roles support and complement each other and can be harmonized to allow

18

19 water quality efforts to be considered and integrated into the growth management process

20

21 outlined in the GMA.

27.

28 The Board concludes Ecology may, within the bounds of the GMA, require use of LID as

29

30 a water quality management tool. The Board further concludes that the Phase I Permit must be

31

32 modified to require use of LID where feasible, as it is necessary to meet the MEP and AKART

33

34 standards of federal and state law, respectively. RCW 36.70A.070(1) already provides the

35

36 mandate for local governments planning under the GMA to address drainage, flooding, and

37

38 stormwater runoff in order to mitigate or cleanse discharges of water pollution. The Permit,

39

40 including the Manual, merely sets forth the methods to accomplish this requirement.

41

1 D. Existing Development (Issue F.2)

2 28.

3 PSA and the Utilities contend that the permit provisions addressing existing development
4 are inadequate to meet the MEP and AKART standards. Their primary complaint is that both the
5 structural and source control provisions applicable to existing development require only that
6 programs "reduce" impacts from discharges (S5.C.6) or that the permittees "reduce" pollutants in
7 runoff (S5.C.7). They contend that these sections do not set any minimum expectation for the
8 level of effort required and allow the permittees to make de minimus reductions in polluting
9 discharges, and thus constitute impermissible self regulation. *PSA v. Ecology*, PCHB Nos. 02-
10 162, -163, and -164, Order Granting Partial Summary Judgment (June 6, 2003)(CL XVI)(citing
11 *Environmental Defense Center v. Environmental Protection Agency*, at U.S. App. 497, at 57-62
12 (9th Cir., Jan. 14, 2003)).

13 29.

14 The Board agrees the structural stormwater control program, as drafted, amounts to
15 impermissible self-regulation. First, the permit fails to require a minimum level of effort for the
16 permittees in the selection and prioritization of structural stormwater projects, and provides no
17 review and approval role for Ecology. Second, the permit fails to comply with the applicable
18 EPA rule and therefore amounts to impermissible self regulation on this basis as well. 40 C.F.R.
19 122.26(d)(2)(iv) requires that "Proposed management programs shall describe priorities for
20 implementing controls." Condition S5.C.6 merely requires the permittees to develop a program
21 within 12 months and provide Ecology a "list of planned individual projects that are scheduled

1 for implementation” during the term of the permit. S5.C.6.b.i. While initial project selection is
2 presumably subject to the MEP and AKART standard of the permit, Ecology plays no role in
3 ensuring these standards are met, even through simple review of the selected projects. The
4 permit does not contain any requirement that permittees describe their project priorities or
5 require that Ecology review the permittees’ structural stormwater control program. Ecology is
6 not expected to approve the municipalities’ prioritization of projects in relation to the pollution
7 reduction requirements of the permit. While Ecology testified that the permit “implied” there
8 needs to be a prioritization of planned structural stormwater control projects, and a schedule
9 reviewed by Ecology (*Moore testimony*), the permit does not expressly state this requirement and
10 the fact sheet explicitly states that “review and approval by Ecology is not a permit requirement.”
11 *Ex. Muni 0002, p. 35*. Thus, the structural stormwater control program is left entirely to the
12 discretion of the municipalities, not only with respect to which projects they initially select, but
13 also in the timing and manner in which they implement the selected projects. Prioritization of
14 projects is particularly important given that Conditions S5 and S6 are based upon actions taken
15 by the permittees and not outcomes, and this structural stormwater control provision is to
16 “address impacts that are not adequately controlled by the other required actions of the SWMP.”
17 Prioritization helps to ensure that the sites where the permittees choose to “act” are meaningful
18 in providing environmental protection. It can also assist to engage the public as a partner in
19 reducing pollutants in discharges and the overall volume of discharges. A community, for
20 example, could request a permittee to focus a project in an area which discharges near shellfish
21 beds. While the Board recognizes that local funding will influence the selection of planned

1 projects and that municipalities must therefore retain local control in the selection process, we
2 conclude that the permit must require permittees to describe the prioritization of their selected
3 projects in order to comply with federal rules, demonstrate compliance with the MEP and
4 AKART standards, and facilitate oversight by Ecology to ensure the legal standards of the permit
5 are applied on a programmatic level. *See Save Lake Sammamish v. Ecology*, PCHB Nos. 95-78
6 & -121, Order Granting Summary Judgment (Dec. 12, 1995).

7 30.

8 In contrast to the structural stormwater control program provisions, the source control
9 program for existing development requires a more rigorous program to reduce pollutants in
10 runoff from areas that discharge to MS4s owned or operated by the permittee, and does not
11 suffer from the same flaws as the structural stormwater control program. The permit requires
12 that Ecology must review and approve the source control program. S5.C.7.b.i. Therefore, the
13 Board concludes that the source control program as drafted meets the MEP and AKART
14 standard.

15 E. Water quality violations (Issues F.1.a., F.2.a., and F.4)

16 PSA and PSE argue, through several different issues, that the permit fails to prevent
17 discharges that violate water quality. *See* F.1.a (permit fails to require LID techniques which
18 results in discharges that violate water quality); F.2.a (permit allows discharges from existing
19 development that violate water quality); F.4 (Permit as a whole allows discharges that violate
20 water quality standards; Prohibition on violations of water quality standards contained in Special
21 Condition S4 conflicts with other provisions of the permit). The Board concludes that the

1 permit, with the amendments directed by the Board to meet AKART and MEP, and with the
2 amendments directed by the Board to the S4.F compliance process,²⁸ is adequately conditioned
3 to comply with state law.

4 F. Timelines for Compliance (Issue F.5)

5 31.

6 The CWA sets out a number of deadlines related to NPDES permits for industrial and
7 large municipal dischargers, including a deadline for EPA to establish regulations setting forth
8 permit application requirements, a deadline for filing permit applications, and a deadline for
9 EPA's approval or denial of the permits. 33 U.S.C. § 1342 (p)(4)(A). The final sentence in 33
10 U.S.C. § 1342 (p)(4)(A) states: "Any such permit shall provide for compliance as expeditiously
11 as practicable, but in no event later than 3 years after the date of issuance of such permit." PSA
12 contends that the Phase I Permit violates this provision.

13 32.

14 The Board has addressed this specific sentence before, in a case involving a challenge to
15 a renewal of the Industrial Stormwater General NPDES Permit. *PSA v. Ecology*, PCHB Nos. 02-
16 162, -163, -164, Order Granting Partial Summary Judgment (June 6, 2003). In that case,
17 involving industrial stormwater discharges, the Board concluded that the reference to
18 "compliance" in the sentence referred to compliance with the permit requirement contained in 33
19 U.S.C. § 1342 (p)(3)(A)(the provision pertaining to industrial stormwater discharges). *PSA* at
20 CL XXI. Applying that same analysis to this case, involving municipal stormwater discharges,

21 ²⁸ These modifications are ordered in the Board's Findings, Conclusions and Order on S4, issued on August 7, 2008.

1 the reference to "compliance" is to 33 U.S.C. § 1342 (p)(3)(B)(the provision establishing the
2 MEP standard for municipal stormwater discharges). Therefore, the question becomes whether
3 the permit allows any actions to occur later than three years after the date of issuance of the
4 permit that are necessary to reduce discharges of pollutants to the maximum extent practicable.

5 33.

6 Several of the conditions of the Phase I Permit allow actions required by the permit to
7 occur more than three years after the date of issuance of the permit. PSA and the Utilities
8 contend that this establishes that the permit violates 33 U.S.C. § 1342 (p)(4)(A). However, this
9 fact alone does not establish a violation of 33 U.S.C. § 1342 (p)(4). PSA and the Utilities, as the
10 parties with the burden of proof, must bring forth evidence establishing that earlier compliance
11 with one of the permit provisions currently allowing implementation outside of the three year
12 statutory window is necessary to meet the MEP standard. Ecology has developed a
13 programmatic permit with multiple components to be implemented throughout the permit cycle
14 which, collectively, represent MEP and AKART. To read the statute as suggested by PSA and
15 the Utilities would inappropriately limit Ecology's ability to include within the permit additional
16 conditions or requirements that may not be practicable within three years but which are
17 reasonable within a longer time frame. The Board concludes that PSA and the Utilities have
18 failed to meet their burden on this issue. The record does not contain sufficient evidence on any
19 specific permit condition to convince the Board that the permit violates 33 U.S.C. § 1342
20 (p)(4)(A).

Any Finding of Fact deemed to be a Conclusion of Law is hereby adopted as such.

Having so found and concluded, the Board enters the following

ORDER

Having concluded that portions of the Phase I Permit are invalid, the Board remands the Phase I Permit to Ecology pursuant to WAC 371-08-540, for modifications consistent with this opinion.

1. Ecology shall modify Special Condition S6.E.7 as follows:

7. Source Control in existing Developed Areas

The SWMP shall include the development and implementation of one or more Stormwater Pollution Prevention Plans (SWPPPs). A SWPPP is a documented plan to identify and implement measures to prevent and control the contamination of discharges of stormwater to surface or ground water. SWPPP(s) shall be prepared and implemented for all Port-owned lands, **except environmental mitigation sites owned by the Port of Tacoma**, that are not covered by either a General Permit or an individual NPDES permit issued by Ecology that covers stormwater discharges.

(modified language is in bold and underlined)

2. With respect to the use of LID, in addition to the specific modifications identified in

No. 1 above, Ecology shall also modify the permit consistent with this opinion as follows :

a. Modify Permit Condition S5.C.5.b to read as follows:

iii. The program must ~~((allow))~~ **require** non-structural preventive actions and source reduction approaches ~~((such as))~~, **including** Low Impact Development Techniques (LID), to minimize the creation of impervious surfaces, and measures to minimize the disturbance of soils and vegetation **where feasible**.

- b. Require permittees to identify barriers to implementation of LID and, in each annual report, identify actions taken to remove barriers identified.
- c. Require permittees to adopt enforceable ordinances that require use of LID techniques where feasible in conjunction with conventional stormwater management methods.
- d. Require permittees to address in their annual report to Ecology under the Phase I Permit, information on the extent to which basin planning is being conducted in their jurisdiction, either voluntarily, or pursuant to GMA or any other requirement.
- e. Require permittees to identify, prior to the next permit cycle or renewal, areas for potential basin or watershed planning that can incorporate development strategies as a water quality management tool to protect aquatic resources.

3. Ecology shall modify Special Condition S5.C.6.b.ii, related to structural Stormwater control programs minimum performance measures, to require that permittees describe the prioritization of their selected projects as required by federal rules, in order to facilitate oversight by Ecology to ensure that the MEP and AKART standards are met on a programmatic level.

07-028, 07-029, 0-030,
07-037

CONCURRENCE AND DISSENT

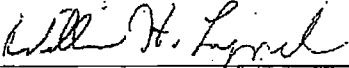

I write separately for the purpose of disagreeing with my colleagues on one portion of the decision. I would allow Pierce County to substitute its monitoring program for the monitoring required under Special Condition S8 (S8). Pierce County provided testimony that it was unable to afford both monitoring programs. Pierce County has established an extensive monitoring program that will allow the County to assess the impacts of stormwater discharges in the

1 receiving water over an extended period of time. Portions of the monitoring program include
2 continuous monitoring, so that a more accurate assessment can be made of the impact of
3 development on the physical channel conditions and aquatic organisms. Ecology has recognized
4 the importance of this type of monitoring in its 2004 report to the Legislature. Ecology's efforts
5 to collect data regarding the effectiveness of BMPs would not significantly suffer from the
6 absence of BMP effectiveness data from Pierce County. To the contrary, I believe that Pierce
7 County's monitoring program would yield information that would be quite valuable to Ecology
8 and assist in the development of future phases of the permit. The one modification I would
9 require to Pierce County's monitoring regime is for Pierce County to test for the full range of
10 chemical pollutants required of other permittees under S8.

11 For this reason, I concur with the remainder of the decision but respectfully dissent
12 regarding Pierce County's monitoring program.

ATTACHMENT 56

Model Post-Construction Stormwater Runoff Control Ordinance

This model ordinance is intended to be a tool for communities who are currently or may soon be responsible for meeting the stormwater management requirements of the National Pollutant Discharge Elimination System (NPDES) regulations. The goal of providing this model ordinance is to assist communities in creating their own stormwater management ordinance. In designing a model stormwater ordinance for a national audience, we purposely avoided creating too complex an ordinance, and instead tried to include suggestions for standard language and concepts that we believe a good stormwater management ordinance should contain. This ordinance should not be construed as an exhaustive listing of all the language needed for a local ordinance, but represents a good base that communities can build upon and customize to be consistent with the staff resources available in their locality. We recommend that you use this document in conjunction with other sources, such as existing ordinances created by other stormwater management programs in your geographic region that have objectives similar to your program's.

Feel free to download and alter any and all portions of this document to meet your needs. Throughout the ordinance, there are sections in which you must insert the name of the agency that you have given regulatory power over stormwater management issues in order to customize it. These sections are denoted by **bold** text placed in brackets. By using this ordinance and customizing these sections, you can create a viable local ordinance with minimal editing.

Italicized text with this symbol ☞ should be interpreted as comments, instructions, or information to assist the ordinance writer. This text *should not appear* in your final ordinance.

Permit Review Process

Model Ordinance for the Control of Post Construction Stormwater Runoff

Table of Contents

Section 1. General Provisions

Section 2. Definitions

Section 3. Permit Procedures and Requirements

Section 4. Waivers

Section 5. General Performance Criteria for Stormwater Management

Section 6. Specific Performance Criteria for Stormwater Treatment Practices

Section 7. Requirements for Stormwater Management Plan Approval

Section 8. Construction Inspection Provisions

Section 9. Maintenance and Repair Requirements

Section 10. Enforcement and Violations

Section 1. General Provisions

1.1. Findings of Fact

It is hereby determined that:

Land development projects and associated increases in impervious cover alter the hydrologic response of local watersheds and increase stormwater runoff rates and volumes, flooding, stream channel erosion, and sediment transport and deposition;

This stormwater runoff contributes to increased quantities of water-borne pollutants, and; Stormwater runoff, soil erosion and nonpoint source pollution can be controlled and minimized through the regulation of stormwater runoff from development sites.

Therefore, the **(jurisdictional stormwater authority)** establishes this set of water quality and quantity policies applicable to all surface waters to provide reasonable guidance for the regulation of stormwater runoff for the purpose of protecting local water resources from degradation. It is determined that the regulation of stormwater runoff discharges from land development projects and other construction activities in order to control and minimize increases in stormwater runoff rates and volumes, soil erosion, stream channel erosion, and nonpoint source pollution associated with stormwater runoff is in the public interest and will prevent threats to public health and safety.

1.2. Purpose

The purpose of this ordinance is to establish minimum stormwater management requirements and controls to protect and safeguard the general health, safety, and welfare of the public residing in

watersheds within this jurisdiction. This ordinance seeks to meet that purpose through the following objectives:

- (1). minimize increases in stormwater runoff from any development in order to reduce flooding, siltation, increases in stream temperature, and streambank erosion and maintain the integrity of stream channels;
- (2). minimize increases in nonpoint source pollution caused by stormwater runoff from development which would otherwise degrade local water quality
- (3). minimize the total annual volume of surface water runoff which flows from any specific site during and following development to not exceed the pre-development hydrologic regime to the maximum extent practicable.
- (4). reduce stormwater runoff rates and volumes, soil erosion and nonpoint source pollution, wherever possible, through stormwater management controls and to ensure that these management controls are properly maintained and pose no threat to public safety.

☞ *The above list is a general set of objectives to reduce the impact of stormwater on receiving waters. The local stormwater authority may wish to set some more specific objectives, based on priority water quality and habitat problems (e.g., to reduce phosphorus loads being delivered to recreational lakes, to sustain a class X trout fishery)*

1.3. Applicability

This ordinance shall be applicable to all subdivision or site plan applications, unless eligible for an exemption or granted a waiver by the **(jurisdictional stormwater authority)** under the specifications of Section 4 of this ordinance. The ordinance also applies to land development activities that are smaller than the minimum applicability criteria if such activities are part of a larger common plan of development that meets the following applicability criteria, even though multiple separate and distinct land development activities may take place at different times on different schedules. In addition, all plans must also be reviewed by local environmental protection officials to ensure that established water quality standards will be maintained during and after development of the site and that post construction runoff levels are consistent with any local and regional watershed plans.

☞ *The size of the site development to which post-construction stormwater management runoff control applies varies but many communities opt for a size limit of 5000 square feet or more. For sites less than 5000 square feet, local officials may wish to grant an exemption as long as the amount of impervious cover created does not exceed 1000 square feet.*

To prevent the adverse impacts of stormwater runoff, the **(jurisdictional stormwater authority)** has developed a set of performance standards that must be met at new development sites. These standards apply to any construction activity disturbing ___ or more square feet of land. The following activities may be exempt from these stormwater performance criteria:

1. Any logging and agricultural activity which is consistent with an approved soil conservation plan or a timber management plan prepared or approved by the

- (appropriate agency), as applicable.
2. Additions or modifications to existing single family structures
 3. Developments that do not disturb more than ____ square feet of land, provided they are not part of a larger common development plan;
 4. Repairs to any stormwater treatment practice deemed necessary by **(jurisdictional stormwater authority)**.

When a site development plan is submitted that qualifies as a redevelopment project as defined in Section 2 of this ordinance, decisions on permitting and on-site stormwater requirements shall be governed by special stormwater sizing criteria found in the current stormwater design manual. This criteria is dependent on the amount of impervious area created by the redevelopment and its impact on water quality. Final authorization of all redevelopment projects will be determined after a review by **(jurisdictional stormwater authority)**.

There are a number of decisions to be made by local communities when addressing the issue of redevelopment and stormwater treatment. The first is defining exactly what qualifies as redevelopment. The definition in Section 2 is from the current Maryland Stormwater Management regulations, and uses the square foot size of the project and its land use classification to establish the definition of a redevelopment project. The second decision involves to what level of stormwater management standards redevelopment projects will be held. Providing cost effective stormwater treatment at redevelopment sites is often a difficult task, and these projects may be given reduced criteria to meet to allow for site constraints. The State of Maryland currently requires that proposed redevelopment project designs include either at least a 20 percent reduction in existing site impervious area, management of at least 20 % of the water quality volume, or some combination of both.

1.4. Compatibility with Other Permit and Ordinance Requirements

This ordinance is not intended to interfere with, abrogate, or annul any other ordinance, rule or regulation, statute, or other provision of law. The requirements of this ordinance should be considered minimum requirements, and where any provision of this ordinance imposes restrictions different from those imposed by any other ordinance, rule or regulation, or other provision of law, whichever provisions are more restrictive or impose higher protective standards for human health or the environment shall be considered to take precedence.

1.5. Severability

If the provisions of any article, section, subsection, paragraph, subdivision or clause of this ordinance shall be judged invalid by a court of competent jurisdiction, such order of judgment shall not affect or invalidate the remainder of any article, section, subsection, paragraph, subdivision or clause of this ordinance.

1.6. Development of a Stormwater Design Manual

The **(jurisdictional stormwater authority)** may furnish additional policy, criteria and information including specifications and standards, for the proper implementation of the

requirements of this ordinance and may provide such information in the form of a Stormwater Design Manual.

This manual will include a list of acceptable stormwater treatment practices, including the specific design criteria and operation and maintenance requirements for each stormwater practice. The manual may be updated and expanded from time to time, at the discretion of the local review authority, based on improvements in engineering, science, monitoring and local maintenance experience. Stormwater treatment practices that are designed and constructed in accordance with these design and sizing criteria will be presumed to meet the minimum water quality performance standards.

☞ *Local communities will need to select the minimum water quality performance standards (e.g., 80% TSS, 40% P) they will require for stormwater treatment practices and place these in their design manual. The 80% removal goal for total suspended solids (TSS) is a management measure developed by EPA as part of the Coastal Zone Act Reauthorization Amendments of 1990. It was selected by EPA for the following factors: (1) removal of 80% is assumed to control heavy metals, phosphorus, and other pollutants; (2) a number of states including DE, FL, TX, MD, and MA require/recommend TSS removal of 80% or greater for new development; and (3) data show that certain structural controls, when properly designed and maintained, can meet this performance level. Further discussion of water quality standards for stormwater management measures can be found in the CZARA Coastal Zone 6217(g) management measures document entitled "Guidance Specifying Management Measures for Sources of Nonpoint Pollution in Coastal Waters" (US EPA, 1993).*

☞ *There are a number of good stormwater design manuals available around the country that communities may wish to refer to in creating their own local manual. Two examples are the new Maryland Department of the Environment 2000 Maryland Stormwater Design Manual Volumes I & II available online at <http://www.mde.state.md.us/environment/wma/stormwatermanual/> and the Stormwater Management Manual for Western Washington, Volumes 1-5 available online at <http://www.ecv.wa.gov/programs/wq/stormwater/manual.html>.*

☞ *Local communities may also wish to consult a new resource available on the Internet called the **Stormwater Managers Resource Center (SMRC)**. This site is dedicated to providing information to stormwater management program managers in Phase II communities to assist in meeting the requirements of the new National Pollutant Discharge Elimination System Phase II regulations. Among the resources available at the website will be a section devoted to supplying guidance on how to build a stormwater manual, including sizing and design criteria. The SMRC website and the manual-builder resources are located at www.stormwatercenter.net.*

Section 2. Definitions

"Accelerated Erosion" means erosion caused by development activities that exceeds the natural processes by which the surface of the land is worn away by the action of water, wind, or chemical action.

“Applicant” means a property owner or agent of a property owner who has filed an application for a stormwater management permit.

“Building” means any structure, either temporary or permanent, having walls and a roof, designed for the shelter of any person, animal, or property, and occupying more than 100 square feet of area.

“Channel” means a natural or artificial watercourse with a definite bed and banks that conducts continuously or periodically flowing water.

“Dedication” means the deliberate appropriation of property by its owner for general public use.

“Detention” means the temporary storage of storm runoff in a stormwater management practice with the goals of controlling peak discharge rates and providing gravity settling of pollutants.

“Detention Facility” means a detention basin or alternative structure designed for the purpose of temporary storage of stream flow or surface runoff and gradual release of stored water at controlled rates.

“Developer” means a person who undertakes land disturbance activities.

“Drainage Easement” means a legal right granted by a landowner to a grantee allowing the use of private land for stormwater management purposes.

“Erosion and Sediment Control Plan” means a plan that is designed to minimize the accelerated erosion and sediment runoff at a site during construction activities.

“Fee in Lieu” means a payment of money in place of meeting all or part of the storm water performance standards required by this ordinance.

“Hotspot” means an area where land use or activities generate highly contaminated runoff, with concentrations of pollutants in excess of those typically found in stormwater.

“Hydrologic Soil Group (HSG)” means a Natural Resource Conservation Service classification system in which soils are categorized into four runoff potential groups. The groups range from A soils, with high permeability and little runoff production, to D soils, which have low permeability rates and produce much more runoff.

“Impervious Cover” means those surfaces that cannot effectively infiltrate rainfall (e.g., building rooftops, pavement, sidewalks, driveways, etc).

“Industrial Stormwater Permit” means an National Pollutant Discharge Elimination System permit issued to a commercial industry or group of industries which regulates the pollutant levels associated with industrial stormwater discharges or specifies on-site pollution control strategies.

“Infiltration” means the process of percolating stormwater into the subsoil.

“Infiltration Facility” means any structure or device designed to infiltrate retained water to the subsurface. These facilities may be above grade or below grade.

“Jurisdictional Wetland” means an area that is inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support a prevalence of vegetation typically adapted for life in saturated soil conditions, commonly known as hydrophytic vegetation.

“Land Disturbance Activity” means any activity which changes the volume or peak flow discharge rate of rainfall runoff from the land surface. This may include the grading, digging, cutting, scraping, or excavating of soil, placement of fill materials, paving, construction,

substantial removal of vegetation,, or any activity which bares soil or rock or involves the diversion or piping of any natural or man-made watercourse.

“Landowner” means the legal or beneficial owner of land, including those holding the right to purchase or lease the land, or any other person holding proprietary rights in the land.

“Maintenance Agreement” means a legally recorded document that acts as a property deed restriction, and which provides for long-term maintenance of storm water management practices.

“Nonpoint Source Pollution” means pollution from any source other than from any discernible, confined, and discrete conveyances, and shall include, but not be limited to, pollutants from agricultural, silvicultural, mining, construction, subsurface disposal and urban runoff sources.

“Offset Fee” means a monetary compensation paid to a local government for failure to meet pollutant load reduction targets.

“Off-Site Facility” means a stormwater management measure located outside the subject property boundary described in the permit application for land development activity.

“On-Site Facility” means a stormwater management measure located within the subject property boundary described in the permit application for land development activity.

“Recharge” means the replenishment of underground water reserves.

“Redevelopment” means any construction, alteration or improvement exceeding ___ square feet in areas where existing land use is high density commercial, industrial, institutional or multi-family residential.

“Stop Work Order” means an order issued which requires that all construction activity on a site be stopped.

“Storm Water Management” means the use of structural or non-structural practices that are designed to reduce storm water runoff pollutant loads, discharge volumes, peak flow discharge rates and detrimental changes in stream temperature that affect water quality and habitat.

“Storm Water Retrofit” means a stormwater management practice designed for an existing development site that previously had either no stormwater management practice in place or a practice inadequate to meet the stormwater management requirements of the site.

“Stormwater Runoff” means flow on the surface of the ground, resulting from precipitation.

“Stormwater Treatment Practices (STPs)” means measures, either structural or nonstructural, that are determined to be the most effective, practical means of preventing or reducing point source or nonpoint source pollution inputs to stormwater runoff and water bodies.

“Water Quality Volume (WQ_v)” means the storage needed to capture and treat 90% of the average annual stormwater runoff volume. Numerically (WQ_v) will vary as a function of long term rainfall statistical data.

“Watercourse” means a permanent or intermittent stream or other body of water, either natural or man-made, which gathers or carries surface water.

Section 3. Permit Procedures and Requirements

3.1. Permit Required.

No land owner or land operator shall receive any of the building, grading or other land development permits required for land disturbance activities without first meeting the requirements of this ordinance prior to commencing the proposed activity.

➤ *The intent is to ensure that no activities that disturb the land are issued permits prior to review and approval of the stormwater management plan. Communities may elect to issue a stormwater management permit separate of any other land development permits required, or, as in this ordinance, tie the issuing of construction permits to the approval of a final stormwater management plan.*

3.2. Application Requirements

Unless specifically excluded by this ordinance, any land owner or operator desiring a permit for a land disturbance activity shall submit to the **(jurisdictional stormwater authority)** a permit application on a form provided for that purpose.

Unless otherwise excepted by this ordinance, a permit application must be accompanied by the following in order that the permit application be considered: a stormwater management concept plan; a maintenance agreement; and a non-refundable permit review fee.

The stormwater management plan shall be prepared to meet the requirements of Sec. 5 of this ordinance, the maintenance agreement shall be prepared to meet the requirements of Sec. 9 of this ordinance, and fees shall be those established by the **(jurisdictional stormwater authority)**.

3.3. Application Review Fees

The fee for review of any land development application shall be based on the amount of land to be disturbed at the site, and the fee structure shall be established by the **(jurisdictional stormwater authority)**. All of the monetary contributions shall be credited to a local budgetary category to support local plan review, inspection and program administration, and shall be made prior to the issuance of any building permit for the development.

➤ *Local communities can use these review fees to raise funds for staff and resources to further their stormwater management programs.*

3.4. Application Procedure

1. Applications for land disturbance activity permits must be filed with the **(appropriate review agency)** on any regular business day.
2. A copy of this permit application shall be forwarded to **(jurisdictional stormwater authority)** for review
3. Permit applications shall include the following: two copies of the stormwater management concept plan, two copies of the maintenance agreement, and any required review fees.
4. Within __ business days of the receipt of a complete permit application, including all documents as required by this ordinance, the **(jurisdictional stormwater authority)** shall inform the applicant whether the application, plan and maintenance agreement are approved or disapproved.

Local officials will need to decide the appropriate time frame for review of an application. This will often be determined by the staff available for permit review and for an inspection of sites undergoing construction.

5. If the permit application, stormwater management plan or maintenance agreement are disapproved, the applicant may revise the stormwater management plan or agreement. If additional information is submitted, the **(jurisdictional stormwater authority)** shall have ___ business days from the date the additional information is received to inform the applicant that the plan and maintenance agreement are either approved or disapproved.
6. If the permit application, final stormwater management plan and maintenance agreement are approved by the **(jurisdictional stormwater authority)**, all appropriate land disturbance activity permits shall be issued.

3.5. Permit Duration

Permits issued under this section shall be valid from the date of issuance through the date the **(jurisdictional stormwater authority)** notifies the permitholder that all stormwater management practices have passed the final inspection required under permit condition.

Section 4. Waivers to Stormwater Management Requirements

4.1. Waivers for Providing Stormwater Management

Every applicant shall provide for stormwater management as required by this ordinance, unless a written request is filed to waive this requirement. Requests to waive the stormwater management plan requirements shall be submitted to the **(jurisdictional stormwater authority)** for approval.

The minimum requirements for stormwater management may be waived in whole or in part upon written request of the applicant, provided that at least one of the following conditions applies:

1. It can be demonstrated that the proposed development is not likely to impair attainment of the objectives of this ordinance.
2. Alternative minimum requirements for on-site management of stormwater discharges have been established in a stormwater management plan that has been approved by the **(jurisdictional stormwater authority)** and the implementation of the plan is required by local ordinance.
3. Provisions are made to manage stormwater by an off-site facility. The off-site facility is required to be in place, to be designed and adequately sized to provide a level of stormwater control that is equal to or greater than that which would be afforded by on-site practices and there is a legally obligated entity responsible for long-term operation and maintenance of the stormwater practice.
4. The **(jurisdictional stormwater authority)** finds that meeting the minimum on-site management requirements is not feasible due to the natural or existing physical characteristics of a site.

5. Non-structural practices will be used on the site that reduce: a) the generation of stormwater from the site, b) the size and cost of stormwater storage and c) the pollutants generated at the site. These non-structural practices are explained in detail in the current design manual and the amount of credit available for using such practices shall be determined by the **(jurisdictional stormwater authority)**.

In instances where one of the conditions above applies, the **(jurisdictional stormwater authority)** may grant a waiver from strict compliance with these stormwater management provisions, as long as acceptable mitigation measures are provided. However, to be eligible for a variance, the applicant must demonstrate to the satisfaction of the **(jurisdictional stormwater authority)** that the variance will not result in the following impacts to downstream waterways:

- Deterioration of existing culverts, bridges, dams, and other structures;
- Degradation of biological functions or habitat;
- Accelerated streambank or streambed erosion or siltation;
- Increased threat of flood damage to public health, life, property .

Furthermore, where compliance with minimum requirements for stormwater management is waived, the applicant will satisfy the minimum requirements by meeting one of the mitigation measures selected by the jurisdictional stormwater authority. Mitigation measures may include, but are not limited to, the following:

- The purchase and donation of privately owned lands, or the grant of an easement to be dedicated for preservation and/or reforestation. These lands should be located adjacent to the stream corridor in order to provide permanent buffer areas to protect water quality and aquatic habitat,
- The creation of a stormwater management facility or other drainage improvements on previously developed properties, public or private, that currently lack stormwater management facilities designed and constructed in accordance with the purposes and standards of this ordinance,
- Monetary contributions (Fee-in-Lieu) to fund stormwater management activities such as research and studies (e.g., regional wetland delineation studies, stream monitoring studies for water quality and macroinvertebrates, stream flow monitoring, threatened and endangered species studies, hydrologic studies, and monitoring of stormwater management practices.

4.2. Fee in Lieu of Stormwater Management Practices.

Where the **(jurisdictional stormwater authority)** waives all or part of the minimum stormwater management requirements, or where the waiver is based on the provision of adequate stormwater facilities provided downstream of the proposed development, the applicant shall be required to pay a fee in an amount as determined by the **(jurisdictional stormwater authority)**.

When an applicant obtains a waiver of the required stormwater management, the monetary contribution required shall be in accordance with a fee schedule (unless the developer and the

stormwater authority agree on a greater alternate contribution) established by the **(jurisdictional stormwater authority)**, and based on the cubic feet of storage required for stormwater management of the development in question. All of the monetary contributions shall be credited to an appropriate capital improvements program project, and shall be made by the developer prior to the issuance of any building permit for the development.

4.3. Dedication of land

In lieu of a monetary contribution, an applicant may obtain a waiver of the required stormwater management by entering into an agreement with the **(jurisdictional stormwater authority)** for the granting of an easement or the dedication of land by the applicant, to be used for the construction of an off-site stormwater management facility. The agreement shall be entered into by the applicant and the **(jurisdictional stormwater authority)** prior to the recording of plats or, if no record plat is required, prior to the issuance of the building permit.

Section 5. General Performance Criteria for Stormwater Management

Unless judged by the **(jurisdictional stormwater authority)** to be exempt or granted a waiver, the following performance criteria shall be addressed for stormwater management at all sites:

- (A). All site designs shall establish stormwater management practices to control the peak flow rates of stormwater discharge associated with specified design storms and reduce the generation of stormwater. These practices should seek to utilize pervious areas for stormwater treatment and to infiltrate stormwater runoff from driveways, sidewalks, rooftops, parking lots, and landscaped areas to the maximum extent practical to provide treatment for both water quality and quantity.

☞ *There are several sources of climatological references that can be consulted to find the rainfall depths for the appropriate design storm intervals (1, 10, 25, and 100 year). The NOAA National Climatological Data Center has a "Summary of the Day" database that can provide rainfall numbers for most major cities and airports in the country. Another possible source is the Urban Hydrology for Small Watersheds. TR-55 (Technical Release 55) published by the Engineering Division, United States Natural Resource Conservation Service (formerly known as the Soil Conservation Service) United States Department of Agriculture, June 1986.*

- (B). All stormwater runoff generated from new development shall not discharge untreated stormwater directly into a jurisdictional wetland or local water body without adequate treatment. Where such discharges are proposed, the impact of the proposal on wetland functional values shall be assessed using a method acceptable to the **(jurisdictional stormwater authority)**. In no case shall the impact on functional values be any less than allowed by the Army Corp of Engineers (ACE) or the **(Appropriate State Agency)** responsible for natural resources.
- (C). Annual groundwater recharge rates shall be maintained, by promoting infiltration through the use of structural and non-structural methods. At a minimum, annual recharge from the

post development site shall mimic the annual recharge from pre-development site conditions.

➤ *Recharge is a relatively new stormwater criteria, and has been implemented so far in the Massachusetts coastal zone and in Maryland. The recharge criteria requires considerable effort to use existing pervious areas for stormwater treatment and infiltration, which means that it must be considered very early in the site design process when basic decisions about layout and vegetative cover are made. For additional discussion of recharge criteria, consult the manual builder on the Stormwater Managers Resource Center (SMRC) at www.stormwatercenter.net.*

- (D). For new development, structural stormwater treatment practices shall be designed to remove ___% of the average annual post development total suspended solids load (TSS). It is presumed that a STP complies with this performance standard if it is:
- sized to capture the prescribed water quality volume (WQ_v).
 - designed according to the specific performance criteria outlined in the local stormwater design manual,
 - constructed properly, and
 - maintained regularly.

➤ *For post construction stormwater runoff, the ability of stormwater management programs to meet federal guidelines under the NPDES regulations will become increasingly important. A local government seeking to manage runoff to achieve water quality standards has a number of options for reaching their goal. The options are listed below, from the most typical standard stormwater quality practice to more advanced program options. Each option has an associated level of effort for the management of stormwater, and the likelihood of realizing water quality treatment goals depends on the option a local government selects. Local governments should assess the option they wish to select in light of new Phase II regulations and the current ability of their stormwater management staff to meet more extensive local/state staff review and inspection requirements.*

Option 1. Require Stormwater Treatment Practices for Stormwater Quality

Many current stormwater programs simply require that the developer install stormwater treatment practices, but do not specify a target for specific pollutant reduction performance. These programs simply require that a standard volume of stormwater be treated (e.g., a half-inch of runoff). Many of these programs also have generous waiver and exemption provisions, so that as much as 25% of all new development can avoid criteria for water quality. Unless the target removal goals are very low, these communities cannot expect their current programs to eliminate net additional pollutants associated with future development.

(See City of Knoxville, TN Stormwater and Street Ordinance, at <http://www.ci.knoxville.tn.us/>)

Option 2. Institute More Rigorous Design Standards for Stormwater Practices.

A number of communities have improved their stormwater programs by strengthening their design standards for stormwater practices. This has involved narrowing the list of acceptable practices to those with a proven ability to remove particular pollutants, increasing the volume of runoff that is treated by each practice (e.g. treat first 1" of stormwater runoff), clamping down on waivers and exemptions (or requiring a fee-in-lieu), and requiring design features that reduce maintenance problems.

The advantage of this program option is that compliance can be presumed as long as designers follow the design rules. It does require a good stormwater manual and more extensive local/state staff review and training. It can achieve significant reduction for some pollutants, such as sediment and nutrients. The disadvantage of the program option is that current stormwater technology may not be effective enough for some pollutants (e.g., bacteria), or capable of reducing the net additional load for high levels from future development.

(For an example see Maryland Department of the Environment 2000 Maryland Stormwater Design Manual available at <http://www.mde.state.md.us/environment/wma/stormwatermanual/>. The states of New York and Vermont are in the process of adopting similar design standards for their manuals).

Option 3. Require On-Site Load Calculation

A handful of communities have adopted an approach whereby the design engineer must calculate pre- and post- development loads for a particular pollutant, and then design a system of practices to meet a load reduction target, based on STP removal rates. Phosphorus has been used in most cases, and the load reduction target varies. This option results in more directed design geared more specifically to the pollutant of concern.

The on-site load calculation option has several disadvantages. First, designers can select to use math modeling to their advantage to reduce costs and come into compliance. Second, technical data to support the program option are limited to just a few parameters, such as phosphorus, nitrogen and sediment. Third, the removal rates for the stormwater practices seldom account for factors where pollutant load removal is compromised, and tend to be optimistic. Lastly, this program option is very intensive in terms of local review and compliance, and requires more staffing to implement.

(For an example of on-site load calculation see the publication Phosphorus Control in Lake Watersheds: A Technical Guide to Evaluating New Development by the Maine Department of Environmental Protection. Another example where this option has been applied is for New York City water supply areas).

Option 4. Load Calculation w/ Stormwater Offset Fee to Provide Retrofits on Existing Development

In this program option, a community requires the on-site load calculation described in Option 3, but is very conservative in the assumptions it allows on loading and removal efficiency. Consequently, designers at most sites cannot fully comply with the load reduction for the requirement at their site. To fully comply, they must pay an offset fee to the local government which is used to support design and construction of stormwater retrofits at existing development in the watershed. The fee is set at the cost of providing an equivalent amount of pollutant removal elsewhere (dollars/pound).

The advantage of this approach is that it provides a means of financing the stormwater retrofits needed to reduce pollutant loads from existing development. It does require greater local staffing to find, design and build the retrofits which offset the loads from new development. If administered properly, this program option can potentially eliminate the net additional load from new development. Several communities currently provide this option for developers, but it is not clear how much revenue has been collected so far.

(This option has been applied in Maryland Critical Areas and Virginia Chesapeake Bay resource management areas. For more information, see the website regarding the Maryland Critical Area Act at <http://www.dnr.state.md.us/criticalarea/> and the Virginia Chesapeake Bay Preservation Area Regulation at <http://www.cblad.state.va.us/regs.htm>)

- (E). To protect stream channels from degradation, a specific channel protection criteria shall be provided as prescribed in the current stormwater manual.

➤ Channel protection is a relatively new criteria, but is increasingly viewed as a critical one due to the mounting evidence that stream channels enlarge in response to watershed development. Studies have found higher bank erosion rates and increased instream sediment loads for urban streams when compared to the 5-20% estimate for the annual sediment budget attributable to bank erosion in rural streams (Walling and Woodward, 1995; Collins et al., 1997). Research also indicates that channel enlargement can begin at a relatively low level of watershed development, as indicated by the amount of impervious cover. One study estimated that channel erosion rates were three to six times higher in a moderately urbanized watershed (14% impervious cover) than in a comparable rural one, with less than 2% impervious cover (Neller, 1988).

The basic methodology to calculate channel enlargement relies on obtaining historical cross-sectional data from past surveys (often obtained from transportation agencies or public works departments that conducted surveys at the time of road construction or improvement projects) and comparing these with current cross-sectional data obtained from field surveys conducted at the time of the study. The approach also utilizes predictive (i.e., empirical) equations to estimate an ultimate channel enlargement ratio once the channel has enlarged sufficiently to be in balance with its hydrological forces.

Basic Options for Stream Channel Protection

Many different design criteria have been suggested to protect downstream channels from erosion. It should be clearly noted that none of these criteria have yet been monitored in the field to demonstrate their effectiveness, and most are based on hydrologic or hydraulic modeling of streams. The three options that appear to hold some promise are:

24 hour detention of the one year storm event. This criteria would result in up to 24 hours of detention for runoff generated by a rainfall depth based on annual rainfall for a region. Smaller storms events would also experience some detention, but probably much less than 24 hours. The premise of this criteria is that runoff would be stored and released in such a gradual manner that critical erosive velocities would seldom be exceeded in downstream channels. The required volume needed for 1 year extended detention is significant; it is roughly equivalent to about 90 to 95% of the required volume needed for ten year peak discharge control. Consequently, the need for two year peak discharge management would be eliminated when the 1 year ED is provided, as long as the ten year peak discharge control is achieved. (For an example, see Maryland Department of the Environment 2000 Maryland Stormwater Design Manual available at <http://www.mde.state.md.us/environment/wma/stormwatermanual/>. The states of New York and Virginia also use this design criteria for stream channel protection in their stormwater design manuals).

Distributed runoff control (DRC): This criteria has been developed by MaCrae (1993) and involves complex field assessments and modeling to determine the hydraulic stress and erosion potential of bank materials. The criteria states that channel erosion is minimized if the alteration in the transverse distribution of erosion potential about a channel parameter is maintained constant with predevelopment values, over the range of available flows, such that the channel is just able to move the dominant particle size of the bed load. This Canadian method holds promise, but has not been tested extensively in the United States and requires significantly greater data collection and modeling than any of the other methods.

(For a discussion of this criteria, see the Vermont Stormwater Management Handbook Technical Support Document- Appendix B, November 2000).

Bankfull capacity/duration criteria: This criteria has been advanced by Tapley et al 1996, and states that the post-development, bankfull flow frequency, duration and depth must be controlled to predevelopment values at a designated control point(s) in the channel. The Rule of thumb for selecting control point(s) is to use a 10: 1 ratio of peak discharge from the one year storm for the developed site to the discharge from the stream for the same frequency storm (Tapley et al, 1996). In theory, this criteria should result in a high level of downstream protection. The practical problem is in defining how the criteria is to be interpreted; whether sub-bankfull events (that typically erode the toe of the streambank) should also be considered; and precisely where the "bankfull" should be measured. For example, the channel of many streams have been modified in the past by prior land uses and channelization, and may not represent the "true" channel. In other cases, the stormwater outfall discharge laterally to a stream, and it is therefore difficult to assign which flows the developer is actually responsible for controlling.

Pros and Cons of Channel Protection Sizing Criteria.

Each of the three options has some limitations. For example, both the DRC and bankfull capacity sizing criteria options lack widely accepted or universal design methodologies. In each case, local stream cross-section and/or soil measurements are needed, and considerable contention between the designer and the reviewer can be expected on how and where the analysis should be performed. Given the many operational problems currently associated with either option, and the lack of a tested design methodology at present, the two options probably deserve further study, but are not ready for wide application.

This leaves only one remaining option-- the one-year 24 hour detention criteria. It, too, has some limitations:

- *results in unacceptably small diameter orifices for sites less than ten acres in size.*
- *requires a storage volume roughly equivalent to that needed for two year control.*
- *has not been "tested" by continuous simulation modeling to determine if acceptable detention times can be achieved for smaller storms can be achieved (1.0 to 1.5 inches).*
- *is only needed in streams that are susceptible to bank erosion.*

Based on the foregoing, it appears that the best option to provide channel protection (C_p) is 12 to 24 hour extended detention of the one-year 24 hour storm event. This C_p requirement only applies to sites greater than ten acres in size. Local governments may wish to retain the option of employing the DRC or bankfull capacity/duration criteria as an alternative, should their analytical and design requirements become more simplified and refined in the future

There are some basic exemptions to where the channel protection criteria should be applied (small drainage areas, direct discharge to tidal waters or a lake, flat terrain etc), and communities must decide how and when this criteria will be required.

- (F). Stormwater discharges to critical areas with sensitive resources (i.e., cold water fisheries, shellfish beds, swimming beaches, recharge areas, water supply reservoirs) may be subject to additional performance criteria, or may need to utilize or restrict certain stormwater management practices.

- (G). Certain industrial sites are required to prepare and implement a stormwater pollution prevention plan, and shall file a notice of intent (NOI) under the provisions of the National Pollutant Discharge Elimination System (NPDES) general permit. The stormwater pollution prevention plan requirement applies to both existing and new industrial sites.

➤ *Applicants and local communities may wish to consult the Environmental Protection Agency website at <http://www.epa.gov/owm/swm/phase2> for more information on Phase II requirements.*

- (H). Stormwater discharges from land uses or activities with higher potential pollutant loadings, known as “hotspots”, may require the use of specific structural STPs and pollution prevention practices.
- (I). Prior to design, applicants are required to consult with the **(jurisdictional stormwater authority)** to determine if they are subject to additional stormwater design requirements.
- (J). The calculations for determining peak flows as found in the Stormwater Design Manual shall be used for sizing all stormwater management practices.

Section 6. Basic Stormwater Management Design Criteria

➤ *Rather than place specific stormwater design criteria into an ordinance, it is often preferable to fully detail these requirements in a stormwater design manual. This allows specific design information to change over time as new information or techniques become available without requiring the formal process needed to change ordinance language. The ordinance can then require those submitting any development application to consult the current stormwater design manual for the exact design criteria for the stormwater management practices appropriate for their site.*

In the Maryland Stormwater Design Manual, for example, there are a set of specified performance criteria for each stormwater management practice, based on six factors:

- *Site Design Feasibility -*
- *Conveyance Issues -*
- *Pretreatment Requirements -*
- *Treatment/Geometry Conditions*
- *Environmental/Landscaping Standards*
- *Maintenance Needs*

Each community will need to decide the specific design and sizing criteria for the stormwater management practices they allow, and select a storm event frequency(1, 2, 10, 100 year) that they believe will meet their stormwater quality and quantity control requirements.

6.1. Minimum Control Requirements

All stormwater management practices will be designed so that the specific storm frequency storage volumes (e.g., recharge, water quality, channel protection, 10 year, 100 year) as identified in the current stormwater design manual are met, unless the **(jurisdictional stormwater authority)** grants the applicant a waiver or the applicant is exempt from such requirements.

In addition, if hydrologic or topographic conditions warrant greater control than that provided by the minimum control requirements, the **(jurisdictional stormwater authority)** reserves the right to impose any and all additional requirements deemed necessary to control the volume, timing, and rate of runoff.

6.2 Site Design Feasibility

Stormwater management practices for a site shall be chosen based on the physical conditions of the site. Among the factors that should be considered:

1. Topography
2. Maximum Drainage Area
3. Depth to Water Table
4. Soils
5. Slopes
6. Terrain
7. Head
8. Location in relation to environmentally sensitive features or ultra-urban areas

Applicants shall consult the Stormwater Design Manual for guidance on the factors that determine site design feasibility when selecting a stormwater management practice.

6.3 Conveyance Issues

All stormwater management practices shall be designed to convey stormwater to allow for the maximum removal of pollutants and reduction in flow velocities. This shall include, but not be limited to:

1. Maximizing of flowpaths from inflow points to outflow points
2. Protection of inlet and outfall structures
3. Elimination of erosive flow velocities
4. Providing of underdrain systems, where applicable

The Stormwater Design Manual shall provide detailed guidance on the requirements for conveyance for each of the approved stormwater management practices.

6.4 Pretreatment Requirements

Every stormwater treatment practice shall have an acceptable form of water quality pretreatment, in accordance with the pretreatment requirements found in the current stormwater design manual. Certain stormwater treatment practices, as specified in the Stormwater Design Manual, are prohibited even with pretreatment in the following circumstances:

- A. Stormwater is generated from highly contaminated source areas known as "hotspots"
- B. Stormwater is carried in a conveyance system that also carries contaminated, non-stormwater discharges
- C. Stormwater is being managed in a designated groundwater recharge area.

D. Certain geologic conditions exist (e.g., karst) that prohibit the proper pretreatment of stormwater.

6.5. Treatment/Geometry Conditions

All stormwater management practices shall be designed to capture and treat stormwater runoff according to the specifications outlined in the Stormwater Design Manual. These specifications will designate the water quantity and quality treatment criteria that apply to an approved stormwater management practice.

6.6. Landscaping Plans Required

All stormwater management practices must have a landscaping plan detailing both the vegetation to be in the practice and how and who will manage and maintain this vegetation. This plan must be prepared by a registered landscape architect or soil conservation district.

6.7. Maintenance Agreements

All stormwater treatment practices shall have an enforceable operation and maintenance agreement to ensure the system functions as designed. This agreement will include any and all maintenance easements required to access and inspect the stormwater treatment practices, and to perform routine maintenance as necessary to ensure proper functioning of the stormwater treatment practice. In addition, a legally binding covenant specifying the parties responsible for the proper maintenance of all stormwater treatment practices shall be secured prior to issuance of any permits for land disturbance activities.

6.8. Non-Structural Stormwater Practices

The use of non-structural stormwater treatment practices is encouraged in order to minimize the reliance on structural practices. Credit in the form of reductions in the amount of stormwater that must be managed can be earned through the use of non-structural practices that reduce the generation of stormwater from the site. These non-structural practices are explained in detail in the current design manual and applicants wishing to obtain credit for use of non-structural practices must ensure that these practices are documented and remain unaltered by subsequent property owners.

Section 7. Requirements for Stormwater Management Plan Approval

7.1. Stormwater Management Plan Required for All Developments.

No application for development will be approved unless it includes a stormwater management plan detailing in concept how runoff and associated water quality impacts resulting from the development will be controlled or managed. This plan must be prepared by an individual

approved by the **(jurisdictional stormwater authority)** and must indicate whether stormwater will be managed on-site or off-site and, if on-site, the general location and type of practices. The stormwater management plan(s) shall be referred for comment to all other interested agencies, and any comments must be addressed in a final stormwater management plan. This final plan must be signed by a licensed professional engineer (PE), who will verify that the design of all stormwater management practices meet the submittal requirements outlined in the Submittal Checklist found in the stormwater design manual. No building, grading, or sediment control permit shall be issued until a satisfactory final stormwater management plan, or a waiver thereof, shall have undergone a review and been approved by the **(jurisdictional stormwater authority)** after determining that the plan or waiver is consistent with the requirements of this ordinance.

➤ *One way to handle the submittal requirements for both the concept plan and the final design plan is to place Submittal Checklists in the stormwater design manual and require that they are used for submission of any plan. The benefit of this is that changes in submittal requirements can be made as needed without needing to revisit and alter the original ordinance. Three model checklists can be found on the Stormwater Managers Resource Center (SMRC) website at www.stormwatercenter.net.*

7.2. Stormwater Management Concept Plan Requirements

A stormwater management concept plan shall be required with all permit applications and will include sufficient information (e.g., maps, hydrologic calculations, etc) to evaluate the environmental characteristics of the project site, the potential impacts of all proposed development of the site, both present and future, on the water resources, and the effectiveness and acceptability of the measures proposed for managing stormwater generated at the project site. The intent of this conceptual planning process is to determine the type of stormwater management measures necessary for the proposed project, and ensure adequate planning for management of stormwater runoff from future development. To accomplish this goal the following information shall be included in the concept plan:

1. A map (or maps) indicating the location of existing and proposed buildings, roads, parking areas, utilities, structural stormwater management and sediment control facilities. The map(s) will also clearly show proposed land use with tabulation of the percentage of surface area to be adapted to various uses; drainage patterns; locations of utilities, roads and easements; the limits of clearing and grading; A written description of the site plan and justification of proposed changes in natural conditions may also be required.

➤ *This project description and site plan requirement includes information normally found in an Erosion and Sediment Control plan. For local governments that do not currently have ESC plan requirements or are looking to upgrade their ESC ordinance language, there is a model Erosion and Sediment Control ordinance located at the SMRC website.*

2. Sufficient engineering analysis to show that the proposed stormwater management measures are capable of controlling runoff from the site in compliance with this ordinance and the specifications of the Stormwater Design Manual.

3. A written or graphic inventory of the natural resources at the site and surrounding area as it exists prior to the commencement of the project and a description of the watershed and its relation to the project site. This description should include a discussion of soil conditions, forest cover, topography, wetlands, and other native vegetative areas on the site. Particular attention should be paid to environmentally sensitive features that provide particular opportunities or constraints for development.
4. A written description of the required maintenance burden for any proposed stormwater management facility.
5. The **(jurisdictional stormwater authority)** may also require a concept plan to consider the maximum development potential of a site under existing zoning, regardless of whether the applicant presently intends to develop the site to its maximum potential.

For development or redevelopment occurring on a previously developed site, an applicant shall be required to include within the stormwater concept plan measures for controlling existing stormwater runoff discharges from the site in accordance with the standards of this Ordinance to the maximum extent practicable.

7.3. Final Stormwater Management Plan Requirements

After review of the stormwater management concept plan, and modifications to that plan as deemed necessary by the **(jurisdictional stormwater authority)**, a final stormwater management plan must be submitted for approval. The final stormwater management plan, in addition to the information from the concept plan, shall include all of the information required in the Final Stormwater Management Plan checklist found in the Stormwater Design Manual. This includes:

1. Contact Information

The name, address, and telephone number of all persons having a legal interest in the property and the tax reference number and parcel number of the property or properties affected.

2. Topographic Base Map

A 1" = 200' topographic base map of the site which extends a minimum of ___ feet beyond the limits of the proposed development and indicates existing surface water drainage including streams, ponds, culverts, ditches, and wetlands; current land use including all existing structures; locations of utilities, roads, and easements; and significant natural and manmade features not otherwise shown.

3. Calculations

Hydrologic and hydraulic design calculations for the pre-development and post-development conditions for the design storms specified in this ordinance. Such calculations shall include (i) description of the design storm frequency, intensity and duration, (ii) time of concentration, (iii) Soil Curve Numbers or runoff coefficients, (iv) peak runoff rates and total runoff volumes for each watershed area, (v) infiltration rates, where applicable, (vi) culvert capacities, (vii) flow velocities, (viii) data on the increase in

rate and volume of runoff for the design storms referenced in the Stormwater Design Manual, and (ix) documentation of sources for all computation methods and field test results.

4. Soils Information

If a stormwater management control measure depends on the hydrologic properties of soils (e.g., infiltration basins), then a soils report shall be submitted. The soils report shall be based on on-site boring logs or soil pit profiles. The number and location of required soil borings or soil pits shall be determined based on what is needed to determine the suitability and distribution of soil types present at the location of the control measure.

5. Maintenance and Repair Plan

The design and planning of all stormwater management facilities shall include detailed maintenance and repair procedures to ensure their continued function. These plans will identify the parts or components of a stormwater management facility that need to be maintained and the equipment and skills or training necessary. Provisions for the periodic review and evaluation of the effectiveness of the maintenance program and the need for revisions or additional maintenance procedures shall be included in the plan.

6. Landscaping plan

The applicant must present a detailed plan for management of vegetation at the site after construction is finished, including who will be responsible for the maintenance of vegetation at the site and what practices will be employed to ensure that adequate vegetative cover is preserved. This plan must be prepared by a registered landscape architect or by the soil conservation district.

7. Maintenance Easements

The applicant must ensure access to all stormwater treatment practices at the site for the purpose of inspection and repair by securing all the maintenance easements needed on a permanent basis. These easements will be recorded with the plan and will remain in effect even with transfer of title to the property.

8. Maintenance Agreement

The applicant must execute an easement and an inspection and maintenance agreement binding on all subsequent owners of land served by an on-site stormwater management measure in accordance with the specifications of this ordinance.

9. Erosion and Sediment Control Plans for Construction of Stormwater Management Measures

The applicant must prepare an erosion and sediment control plan for all construction activities related to implementing any on-site stormwater management practices.

10. Other Environmental Permits

The applicant shall assure that all other applicable environmental permits have been acquired for the site prior to approval of the final stormwater design plan.

7.4. Performance Bond/Security

The **(jurisdictional stormwater authority)** may, at its discretion, require the submittal of a performance security or bond prior to issuance of a permit in order to insure that the stormwater

practices are installed by the permit holder as required by the approved stormwater management plan. The amount of the installation performance security shall be the total estimated construction cost of the stormwater management practices approved under the permit, plus 25%. The performance security shall contain forfeiture provisions for failure to complete work specified in the stormwater management plan.

The installation performance security shall be released in full only upon submission of "as built plans" and written certification by a registered professional engineer that the stormwater practice has been installed in accordance with the approved plan and other applicable provisions of this ordinance. The **(jurisdictional stormwater authority)** will make a final inspection of the stormwater practice to ensure that it is in compliance with the approved plan and the provisions of this ordinance. Provisions for a partial pro-rata release of the performance security based on the completion of various development stages can be done at the discretion of the **(jurisdictional stormwater authority)**.

➤ *Some communities elect to also require a maintenance performance security. This bond typically is set at the maintenance costs estimated in the stormwater plan for the period during which the permit holder has maintenance responsibility and is released when the responsibility for practice maintenance is passed on to another party, via an approved maintenance agreement.*

Section 8. Construction Inspection

8.1. Notice of Construction Commencement

The applicant must notify the **(jurisdictional stormwater authority)** in advance before the commencement of construction. Regular inspections of the stormwater management system construction shall be conducted by the staff of the **(jurisdictional stormwater authority)** or certified by a professional engineer or their designee who has been approved by the jurisdictional stormwater authority. All inspections shall be documented and written reports prepared that contain the following information:

1. The date and location of the inspection;
2. Whether construction is in compliance with the approved stormwater management plan
3. Variations from the approved construction specifications
4. Any violations that exist

If any violations are found, the property owner shall be notified in writing of the nature of the violation and the required corrective actions. No added work shall proceed until any violations are corrected and all work previously completed has received approval by the **(jurisdictional stormwater authority)**.

8.2. As Built Plans

All applicants are required to submit actual "as built" plans for any stormwater management practices located on-site after final construction is completed. The plan must show the final design specifications for all stormwater management facilities and must be certified by a

professional engineer. A final inspection by the **(jurisdictional stormwater authority)** is required before the release of any performance securities can occur.

8.3. Landscaping and Stabilization Requirements

Any area of land from which the natural vegetative cover has been either partially or wholly cleared or removed by development activities shall be revegetated within ten (10) days from the substantial completion of such clearing and construction. The following criteria shall apply to revegetation efforts:

Reseeding must be done with an annual or perennial cover crop accompanied by placement of straw mulch or its equivalent of sufficient coverage to control erosion until such time as the cover crop is established over ninety percent (90%) of the seeded area.

Replanting with native woody and herbaceous vegetation must be accompanied by placement of straw mulch or its equivalent of sufficient coverage to control erosion until the plantings are established and are capable of controlling erosion.

Any area of revegetation must exhibit survival of a minimum of seventy-five percent (75%) of the cover crop throughout the year immediately following revegetation.

Revegetation must be repeated in successive years until the minimum seventy-five percent (75%) survival for one (1) year is achieved.

In addition to the above requirements, a landscaping plan must be submitted with the final design describing the vegetative stabilization and management techniques to be used at a site after construction is completed. This plan will explain not only how the site will be stabilized after construction, but who will be responsible for the maintenance of vegetation at the site and what practices will be employed to ensure that adequate vegetative cover is preserved. This plan must be prepared by a registered landscape architect or by the soil conservation district, and must be approved prior to receiving a permit.

Section 9. Maintenance and Repair of Stormwater Facilities

☞ *A model operation and maintenance ordinance for stormwater facilities is also available at the SMRC website. This ordinance goes into greater detail on the elements needed to create an effective stormwater maintenance ordinance. Requirements for inspection are also included in the model.*

9.1. Maintenance Easement

Prior to the issuance of any permit that has an stormwater management facility as one of the requirements of the permit, the applicant or owner of the site must execute a maintenance easement agreement that shall be binding on all subsequent owners of land served by the stormwater management facility. The agreement shall provide for access to the facility at reasonable times for periodic inspection by the **(jurisdictional stormwater authority)**, or their contractor or agent, and for regular or special assessments of property owners to ensure that the

facility is maintained in proper working condition to meet design standards and any other provisions established by this ordinance. The easement agreement shall be recorded by the **(jurisdictional stormwater authority)** in the land records.

9.2. Maintenance Covenants

Maintenance of all stormwater management facilities shall be ensured through the creation of a formal maintenance covenant that must be approved by the **(jurisdictional stormwater authority)** and recorded into the land record prior to final plan approval. As part of the covenant, a schedule shall be developed for when and how often maintenance will occur to ensure proper function of the stormwater management facility. The covenant shall also include plans for periodic inspections to ensure proper performance of the facility between scheduled cleanouts.

The **(jurisdictional stormwater authority)**, in lieu of an maintenance covenant, may accept dedication of any existing or future stormwater management facility for maintenance, provided such facility meets all the requirements of this chapter and includes adequate and perpetual access and sufficient area, by easement or otherwise, for inspection and regular maintenance.

9.3. Requirements for Maintenance Covenants

All stormwater management facilities must undergo, at the minimum, an annual inspection to document maintenance and repair needs and ensure compliance with the requirements of this ordinance and accomplishment of its purposes. These needs may include; removal of silt, litter and other debris from all catch basins, inlets and drainage pipes, grass cutting and vegetation removal, and necessary replacement of landscape vegetation. Any maintenance needs found must be addressed in a timely manner, as determined by the **(jurisdictional stormwater authority)**, and the inspection and maintenance requirement may be increased as deemed necessary to ensure proper functioning of the stormwater management facility.

9.4. Inspection of Stormwater Facilities

Inspection programs may be established on any reasonable basis, including but not limited to: routine inspections; random inspections; inspections based upon complaints or other notice of possible violations; inspection of drainage basins or areas identified as higher than typical sources of sediment or other contaminants or pollutants; inspections of businesses or industries of a type associated with higher than usual discharges of contaminants or pollutants or with discharges of a type which are more likely than the typical discharge to cause violations of state or federal water or sediment quality standards or the NPDES stormwater permit; and joint inspections with other agencies inspecting under environmental or safety laws. Inspections may include, but are not limited to: reviewing maintenance and repair records; sampling discharges, surface water, groundwater, and material or water in drainage control facilities; and evaluating the condition of drainage control facilities and other stormwater treatment practices.

9.5. Right-of-Entry for Inspection

When any new drainage control facility is installed on private property, or when any new connection is made between private property and a public drainage control system, sanitary sewer or combined sewer, the property owner shall grant to the **(jurisdictional stormwater authority)** the right to enter the property at reasonable times and in a reasonable manner for the purpose of inspection. This includes the right to enter a property when it has a reasonable basis to believe that a violation of this ordinance is occurring or has occurred, and to enter when necessary for abatement of a public nuisance or correction of a violation of this ordinance.

9.6. Records of Installation and Maintenance Activities.

Parties responsible for the operation and maintenance of a stormwater management facility shall make records of the installation and of all maintenance and repairs, and shall retain the records for at least ___ years. These records shall be made available to the (jurisdictional stormwater authority) during inspection of the facility and at other reasonable times upon request.

9.7 Failure to Maintain Practices

If a responsible party fails or refuses to meet the requirements of the maintenance covenant, the **(jurisdictional stormwater authority)**, after reasonable notice, may correct a violation of the design standards or maintenance needs by performing all necessary work to place the facility in proper working condition. In the event that the stormwater management facility becomes a danger to public safety or public health, the **(jurisdictional stormwater authority)** shall notify the party responsible for maintenance of the stormwater management facility in writing. Upon receipt of that notice, the responsible person shall have ___ days to effect maintenance and repair of the facility in an approved manner. After proper notice, the **(jurisdictional stormwater authority)** may assess the owner(s) of the facility for the cost of repair work and any penalties; and the cost of the work shall be a lien on the property, or prorated against the beneficial users of the property, and may be placed on the tax bill and collected as ordinary taxes by the county.

Section 10. Enforcement and Penalties.

10.1. Violations

Any development activity that is commenced or is conducted contrary to this Ordinance, may be restrained by injunction or otherwise abated in a manner provided by law.

10.2. Notice of Violation.

When the **(jurisdictional stormwater authority)** determines that an activity is not being carried out in accordance with the requirements of this Ordinance, it shall issue a written notice of violation to the owner of the property. The notice of violation shall contain :

(1) the name and address of the owner or applicant;

- (2) the address when available or a description of the building, structure or land upon which the violation is occurring;
- (3) a statement specifying the nature of the violation;
- (4) a description of the remedial measures necessary to bring the development activity into compliance with this Ordinance and a time schedule for the completion of such remedial action;
- (5) a statement of the penalty or penalties that shall or may be assessed against the person to whom the notice of violation is directed;
- (6) a statement that the determination of violation may be appealed to the municipality by filing a written notice of appeal within fifteen (15) days of service of notice of violation.

10.3. Stop Work Orders

Persons receiving a notice of violation will be required to halt all construction activities. This "stop work order" will be in effect until the **(jurisdictional stormwater authority)** confirms that the development activity is in compliance and the violation has been satisfactorily addressed. Failure to address a notice of violation in a timely manner can result in civil, criminal, or monetary penalties in accordance with the enforcement measures authorized in this ordinance.

10.4. Civil and Criminal Penalties

In addition to or as an alternative to any penalty provided herein or by law, any person who violates the provisions of this Ordinance shall be punished by a fine of not less than _____ Dollars (\$xx) or by imprisonment for a period not to exceed ___ (xx) days, or both such fine and imprisonment. Such person shall be guilty of a separate offense for each day during which the violation occurs or continues.

10.4. Restoration of lands

Any violator may be required to restore land to its undisturbed condition. In the event that restoration is not undertaken within a reasonable time after notice, the **(jurisdictional stormwater authority)** may take necessary corrective action, the cost of which shall become a lien upon the property until paid.

10.5. Holds on Occupation Permits

Occupation permits will not be granted until a corrections to all stormwater practices have been made and accepted by the **(jurisdictional stormwater authority)**.
